Preliminary Fatality Results -- Mountaineer Wind Energy Center, WV.....	18
Preliminary Comparison of Nocturnal Passage Rates and Bat Fatalities in Pennsylvania and West Virginia.....	21
Bats and Wind Turbines: infrared analysis of abundance, flight patterns and avoidance behavior.....	22
Wrap-up: Current Knowledge and Next Steps.....	24
Session I: Questions and Observations.....	26
SESSION II: UPDATE ON THE ALTAMONT	32
Developing Methods to Reduce Bird Fatalities at the Altamont Pass Wind Resource Area.....	32
Study Plan for Effectiveness of Potential Management Methods to Reduce Bird Risk.....	37
Session II - Questions and Observations.....	40
SESSION III: HABITAT EFFECTS FROM TALL STRUCTURES ON PRAIRIE BIRDS	41
Prairie Grouse and Elevated Structures: An Environmental Planning Challenge.....	41
Structural Additions and their Effects on Birds.....	43
Information Review: Habitat Impacts of Wind Power on Sage Grouse.....	45
The Cottler Mountain Sage Grouse Study.....	47
Methods and Metrics for Understanding Indirect Impacts from Wind Projects.....	49
Session III - Questions and Observations.....	52
SESSION IV: BIRD MIGRATION	57
Bird Migration and Wind Power Development: A Spatial-Dependent Perspective ...	57
Migrating Birds and Wind Power.....	59
Songbird Migration in the West.....	61
Attraction of Night Migrating Birds to FAA and other Types of Lights.....	62
Spatial and Temporal Dynamics of Raptor Migration in North America.....	64
Linking Risks Across the Landscape: Developing a Regional Perspective.....	68
Session IV - Questions and Observations.....	70

SESSION V: WHAT TOOLS ARE AVAILABLE AND WHAT DO EACH OF THESE TOOLS OFFER?	75
Application of Radar and Other Tools on Avian Species	75
Application of Thermal Imaging, Acoustics and other Tools on Bat Species	77
Review of Strengths, Weaknesses, and Application of Tools	79
Session V - Questions and Observations	81
Comment/Question for All Participants	82
SESSION VI - RISK ASSESSMENT	83
Overview of Risk Assessment	83
Application of Risk Assessment Tools: Avian Risk of Collision Model	86
Phase I Avian Risk Assessment for Wind Power Facilities	88
Design-Based Quantitative Characterization of Risks for Birds for Existing and New Wind Projects	90
Quantitative Risk Assessments for Proposed Wind Turbine Projects: Utilization and Avoidance/Mortality Model	92
Session VI - Questions and Observations	94
SESSION VII – PRACTICAL APPLICATION	97
APPENDIX A: MEETING PARTICIPANTS	100
APPENDIX B: MEETING AGENDA	113

INTRODUCTION

This is the fifth in a series of meetings organized by the National Wind Coordinating Committee (NWCC)'s Wildlife Workgroup (formerly the Avian Subcommittee). Bringing together representatives from government and non-government organizations, from private business, and from academia, these meetings are convened to examine current research on the impacts of wind energy development on wildlife and to discuss the most effective ways to mitigate such impacts. Earlier meetings focused on birds; the scope has been expanded to examine study methods and metrics, impacts and mitigation strategies related to bats and other wildlife.

Wind energy is able to generate electricity without many of the environmental impacts (conventional and toxic air pollution and greenhouse gases, water use and pollution, and habitat destruction) associated with other energy sources. This can significantly benefit birds, bats, and many other plant and animal species. However, the direct and indirect local impacts of wind plants on birds and bats continue to be an issue. The populations of many bird and bat species are experiencing long-term declines, due to the effects of a wide range of human activities, including energy production and consumption.

Objectives of the Meeting

The objectives of the Wildlife Research Meeting are: to bring the community of stakeholders up to date on the research being done to understand the interaction of birds, bats, and other wildlife with wind energy development; to look at what we've learned about ways to minimize or mitigate wind energy's impacts on wildlife; and, to identify gaps in knowledge and research needs.

Introductory Comments

Dick Anderson, CEC wildlife biologist, Chair, NWCC Wildlife Workgroup. This is our fifth planning meeting. We have found broad stakeholder participation to be productive, especially when it comes to identifying solutions and research needs. The presenters we will hear from today and tomorrow will be giving us progress reports and reviewing what we've learned from ongoing research. Together we will be talking about what we hope to learn as we take this research forward into the future.

Bear in mind that some of these presentations are preliminary. In many cases, presenters are reporting preliminary findings from fieldwork conducted this fall. Please be fair and honest when using information presented here and when reporting it out.

Abby Arnold, Facilitator, RESOLVE, Inc. Like the National Wind Coordinating Committee, those of you participating in this meeting represent the wide range of interests concerned with wind energy, both its benefits and its impacts. Collectively, you share a desire to foster the development of wind energy as a clean, renewable alternative to fossil fuel while minimizing the impacts of wind energy facilities on bird and bat populations.

Ten years ago, the NWCC started an Avian Subcommittee, having identified avian interaction with wind energy development as a primary concern. The group has since broadened its focus and now functions as the NWCC Wildlife Workgroup. The Workgroup's organizing committee was responsible for planning this meeting, deciding on the topics and issues to be addressed, and identifying panelists and moderators to invite. If anyone has any questions or concerns about the structure or conduct of the meeting, please bring them to my attention, and I will bring them up with the organizing committee.

Process Guidelines

The Facilitator reviewed the draft agenda circulated before the workshop (Appendix B). There were no suggestions for changes. The format was a series of plenary sessions, each devoted to a specific topic. Panel moderators coordinated the presentations, and questions were fielded by panel participants after all presenters for a particular session had completed their formal presentations. These Proceedings present summaries of each presentation (presentation slides may be downloaded from www.nationalwind.org as a series of separate Powerpoint files), with question and answer sessions summarized at the end of each section.

The following ground rules for the workshop were proposed by the Facilitator and accepted by the group:

- All parties participate and will be acknowledged by the facilitator.
- Comments may not take the form of a personal attack.
- Participants should feel free to express their own opinions while respecting other points of view.
- No party will report or characterize any comment made in the meeting by any other party in public statements, in discussions with the press, or in other venues outside of this meeting.
- A meeting summary and proceedings will be prepared by the Facilitator. The meeting summary will document each presentation and will summarize discussions. Panel presentation and discussion summaries will be reviewed by panel moderators and participants, and a review draft of the complete Proceedings will be circulated to all meeting attendees prior to being finalized and made available to the public.

Research Meeting Participants

The following is a list of the people who took part in Wildlife Research Meeting V, along with their organizational affiliations. Also noted are the following:

- ^W indicates a member of the Wildlife Workgroup;
- ^P indicates a panel moderator or presenter.

SESSION I: STUDIES CONDUCTED OR TO BE CONDUCTED ON BATS

Moderator: Merlin Tuttle, Bat Conservation International

This session consisted of seven presentations, framed by an Overview of Current Issues and Research Needs and a Wrap-up of Current Knowledge and Next Steps presented by the panel moderator.

- Overview of Available Mortality Studies *Greg Johnson, WEST, Inc.*
- Introduction of Bats and Wind Energy Cooperative *Ed Arnett, BCI*
- New Protocol for Mortality Monitoring *Wally Erickson, WEST, Inc.*
- Patterns from Daily Mortality Searches at Meyersdale, PA *Wally Erickson, WEST, Inc.*
- Patterns from Daily Mortality Searches at Backbone Mountain, WV *Jessica Kerns, University of Maryland*
- Preliminary Radar Observations of Fall Passage Rates vs. Daily Mortality Searches at Backbone Mountain, WV *Brian Cooper, ABR, Inc.*
- Thermal Imaging Observations of Bat and Insect Behavior Relative to Mortality at Backbone Mountain, WV *Jason Horn and Tom Kurz, Boston University*

Overview of Current Issues and Research Needs

presented by
Merlin Tuttle, Bat Conservation International

Panel moderator Merlin Tuttle introduced this panel with a note of thanks to the presenters, who put great effort into designing studies, collecting data. In many cases, these researchers have only just finished compiling data collected this summer and early fall, to be able to present findings from this year's fieldwork.

Why bats merit being on the agenda. Bats comprise nearly a quarter of world's mammal species. Diverse in appearance, behavior, and ecological needs, bats are important to American farmers as essential predators of night-flying pests.

Before the arrival of European settlers on this continent, some bats may have rivaled

passenger pigeons. But bats are vulnerable because they are relatively long-lived mammals, slow to reproduce. One of the formerly most abundant species, the Indiana bat, is now endangered. (The population has dropped from millions in single caves to about 350,000 range wide.) The formerly abundant Gray bat also has become endangered. The Red bat, still widely distributed, has experienced an apparently dramatic population decline. In the 1870s, Edgar Burns noted that it took days for Red bats to migrate over New York State, a phenomenon that no one has seen in our lifetime. (That magnitude would be hard to miss.)

We are here today because all of us recognize a serious need to develop renewable energy. But energy must be developed in a manner that is compatible with preserving wildlife and the health of our environment. Our goal is to share preliminary findings, identify knowledge gaps, and suggest next steps. The findings to be presented here today include the first of their kind in many cases.

Overview of Available Bat Mortality Studies at Wind Energy Projects

presented by
Greg Johnson, WEST, Inc.

The United States has approximately 125 multiple-turbine wind energy facilities in place, with commercial projects completed so far in 32 states. Bat fatalities have been documented at nearly all wind energy facilities in the U.S., but bat mortality estimates have been made only for 11 of these projects, and studies to specifically examine bat interactions with wind projects have so far been conducted at only six sites. This presentation summarizes what has been found at the following project sites:

REGION/ Project site	Topography and Habitat	Number and Size of Turbines
MIDWEST		
Buffalo Ridge, MN	Relatively flat: crop fields, CRP, pasture	281 - 750 kW
Lincoln, WI	Flat crop fields	31 - 660 kW
Top of Iowa	Relatively flat crop fields	89 - 900 kW
ROCKY MOUNTAINS		
Foots Creek Rim, WY	Rim top: short grass prairie; forested areas within 1 mile	133 - 660 kW and 750 kW
Poncaquin, CO*	Relatively flat short grass prairie	44 - 660 kW and 750 kW
PACIFIC NORTHWEST		
Stateline,	Rolling hills and ridges; grasslands,	399 - 660 kW

OR/WA*	shrublands, croplands	
Klondike, OR*	Flat crop fields	16 – 1.5 MW
Vansycle, OR*	Ridges: crop fields and grasslands	38 – 660 kW
Nine Canyon, WA*	Rolling hills and ridges: grasslands, shrublands, croplands	37 – 1.3 MW
EAST		
Buffalo Mountain, TN	Ridge top: reclaimed mined land in forested area	3 – 660 kW
Backbone Mtn, WV	Forested ridge top	<i>Described in detail in separate presentation</i>
Meyersdale, PA	Forested ridge top	<i>Described in detail in separate presentation</i>

* Bat findings incidental to bird studies; no bat mortality estimate made for this site.

Region	Installed Capacity # of Turbines per MW output/year	Mean # Fatalities / Turbine
MIDWEST 4 studies (at 3 sites)	254 MW installed capacity -- .63 turbines per MW per year	1.7
Rocky Mountains 2 studies	68 MW installed capacity -- .6 turbines per MW per year	1.2
Pacific Northwest 4 studies	397 MW installed capacity -- .7 turbines per MW per year	1.2
EAST 2 studies	68 MW installed capacity -- 1.45 turbines per MW per year	46.3

Methodology

Carcass searches were conducted and fatality estimates in most cases adjusted to account for searcher efficiency and carcass removal rates. At Buffalo Ridge, MN, Foote Creek Rim, WY, and Buffalo Mountain, TN, bat use was measured using mist nets and bat echolocation detectors. At Lincoln, WI, thermal (infrared) cameras were also used. At the four Northwestern sites and the Ponsequin, CO case study, bat mortality estimates were incidental to bird studies and – with the exception of limited bat acoustical surveys conducted for a month at the Top of Iowa site – bat use was not measured at these sites.

Mortality surveys have also been conducted at small wind projects sited on farmland in NY (2) and PA (1), and in forested habitats in MA (1) and VT (1). Only one bat fatality (a little brown bat) was found, at the Pennsylvania site. A handful of bat fatalities have been found in the course of extensive (raptor-focused) mortality surveys conducted at older wind farms in open habitat in California.

Findings

In general, bat mortality rates are highest in forested environments such as those found in the East, moderate in open areas close to forests (typical of Midwestern sites), and lowest in open areas (Rocky Mountain states and Pacific Northwest). Differences may be due to region, habitat, bat population sizes, combinations of these factors, or other factors altogether. Available data from existing wind developments suggest that migrant tree bats are most at risk, namely the hoary, eastern red, and silver-haired bats. There are, however, regional differences in species composition. (For example, eastern pipistrelle fatalities were among the most common at Buffalo Mountain, TN.) Bat fatalities occur primarily in late summer and early fall at most wind developments, with a peak in August, during bat migration periods. Estimated annual per-turbine mortality ranged from a high of 47.5 bats per turbine (Backbone Mountain) to a low of 0.7 bats per turbine (Vansycle, OR).

Various other findings include the following:

- Buffalo Mountain, TN, differed from other sites in that bat activity was positively correlated with mortality levels, and mist net surveys showed relatively similar species composition as turbine fatalities. (Although fatalities occurred during the migration period, it is not known whether migrating or foraging bats were involved.) Bat activity decreased as mean nightly wind speeds increased.
- At Lincoln, WI, no bats were observed circling the turbines, acting confused, or foraging at the red lights on top of the turbines.
- At the Top of Iowa project, Anabat (echolocation) data indicated no difference in activity between crop fields with and without turbines, suggesting that turbines did not attract bats.

Research Needs / Questions

- Studies conducted to date in the West and Midwest suggest relatively low levels of mortality in non-forested habitats; however, these data should not be extrapolated to forested environments in the West and Midwest where wind projects are planned.
- There is no data from the southwest (Southern California and Texas).
- What can be done to assess risk to bats during pre-construction studies? Rigorous analysis of a few sites using several methods may prove more useful than many small studies at several sites.
- What affect does collision mortality have on bat populations? We cannot put this in perspective without more data on bat population sizes. In particular, we need to look at the potential for wind power to impact listed bats, especially (in the Eastern U.S.) the endangered Indiana bat.
- Possible collision factors – such as weather conditions, habitat, and turbine operation -- need to be determined. Shorter intervals (e.g., 1-2 days) between carcass searches (at least for a subset of turbines) are required to allow for such correlations to be made.
- More scavenger removal and searcher efficiency trials overlapping fatality search periods are needed to refine mortality estimates.
- Bat behavior near turbines needs to be documented and better understood so that we can begin to develop methods to repel bats, and eliminate or mitigate mortality.

Cooperative Efforts to Assess the Impact of Wind Power on Bats

presented by

Edward B. Arnett, Bat Conservation International

Bat mortality [at wind energy projects] has been with us for some time. It first was documented in Australia in 1972, but only recently has come up as an issue to be studied and addressed. A lot of the studies we have available to us were not designed for bats, but mortality was documented incidentally, so that these findings raise more questions than they answer. It is important to learn from past experiences and to move forward.

While bat mortality has been estimated to be relatively low (<2 bats/turbine/year) at many sites, particularly in the West, large numbers of bat fatalities from Buffalo Mountain, TN and the Mountaineer wind facility at Backbone Mountain, WV (47.5 bats/turbine/year) have brought the issue of bat-wind energy interaction to the forefront.

In response to growing awareness of the potential for wind energy-related bat fatalities, the Bats and Wind Energy Cooperative (BWEC) was formed in 2003 by Bat Conservation International (BCI), US Fish and Wildlife Service (US FWS), the American Wind Energy Association (AWEA), and the US Department of Energy's National Renewable Energy Laboratory (NREL). An alliance of state and federal agencies, private industry, academic institutions, and non-governmental organizations, BWEC's members cooperate to develop solutions to minimize or, where possible, to prevent mortality of bats at wind turbines. BWEC's role is to set priorities, implement and provide peer review of required research, and develop uniform standards and methodologies for assessing risks and mortality. Since its inception less than a year ago, BWEC has launched a focused research effort to understand bat interactions with wind turbines and to develop solutions.

In February 2004, a meeting of bat experts and wind energy developers was held in Florida to discuss problems, knowledge gaps, and studies that might address those gaps. Cooperative funding for this year's research efforts was secured from the following partners: AWEA, BCI, Community Foundation for the Alleghenies, FPL Energy, Massachusetts Technology Collaborative, New York State Energy Research and Development Authority, PPM Energy, and the Rhode Island Renewable Energy Fund.

Why collaborate?

Working relationships are critical, both for enabling stakeholders to find common ground, and for bringing together the resources necessary to conduct the kind of research that is needed. (There are a lot of smaller research efforts ongoing, but research efforts needed to understand bat-wind energy interactions and to avoid, minimize, or mitigate negative impacts are expensive and logistically challenging to implement.) In addition, collaboration enhances the credibility of findings, which is very important for both wildlife conservation and wind energy development. In the case of wind project developers, "data is the currency required to purchase continued public license to operate."

BWEC's committee structure includes an Oversight Committee, a Scientific Advisory Committee (primarily from the academic community) and a Technical Advisory Committee that includes both agency and industry representatives. The coordinator administers the cooperative's activities and facilitates advisory committee activities, ensures that research protocols, proposals, and other documents are peer-reviewed, and coordinates activities designed to disseminate information among BWEC partners and diverse audiences.

BWEC maintains a running list of peer reviewers, including specialists in radar-avian acoustics, study design and analysis. Information about BWEC, including the Cooperative's charter, a bibliography of available literature, results of research, and upcoming meetings and symposia are posted on the organization's website: <http://www.batcon.org/wind/>.

This year's research effort was pulled together on extremely short notice. Funding was pulled together between the February "experts" meeting and June of this year for this summer's research. Priorities identified included:

- Conducting daily carcass searches
- Understanding how bats interact with turbines
- Assessing different methods and tools for understanding bat-turbine interactions and fatalities.

The study proposal for intensive fatality searches to determine bat mortality at wind energy facilities during the fall migration period was developed by Wally Erickson and Jessica Kerns. The protocol was peer-reviewed, and some adjustments were made after field visits to account for varying vegetative and topographic conditions. The study consisted of an intensive six-week effort during the period when reported mortality is highest, from late-July to mid-September. (Erickson's and Kerns' findings will be presented during this session.)

Researchers tested a carcass search protocol that included daily and weekly searches by human observers, as well as the use of dogs to find bat carcasses. The daily carcass searches along with the tools used to monitor bat activity (thermal imaging, radar, and night-vision goggles) allowed us to correlate mortality with weather conditions, turbine characteristics, and other factors. Thermal imaging generated our first look at bat interactions with turbines. Day-to-day anecdotal observations enhanced our understanding. For example, we were able to observe local bats foraging in parts of forested areas that had been cleared for wind turbines.

These data will help us begin to understand bat interactions with turbines and to design experiments to test potential solutions. However, it is important to bear in mind that these are preliminary results; we haven't yet had a chance to model all the complex relationships. Also, because we looked only at a six-week period, findings from this study

cannot be extrapolated to temporal mortality patterns. Other caveats: sample sizes were small, and inferences are limited to the study sites. However, we can use findings from these sites to develop further hypotheses and to begin thinking about pre-construction risk assessment.

Noting that he had spent 14 years in Oregon, including seven years working with the timber industry, the presenter noted that a similar collaborative effort had not been employed to deal with understanding the impact of timber harvest on the northern spotted owl prior to its Federal listing as a threatened species. He suggested that BWTIC offers an opportunity to work proactively with diverse stakeholders toward solutions to avoid some of the "train wrecks" that could derail the wind industry or the future of bat species.

Bat Fatality Monitoring Methods: Fall 2004 Mountaineer and Meyersdale

presented by
Wally Erickson, WEST, Inc.

This presentation summarizes the bat fatality monitoring methods tested over a six-week period (July 31–September 13, 2004) at two wind energy project sites in West Virginia and Pennsylvania. Preliminary results from these monitoring efforts are presented separately.

Study Objectives

The basic protocol was to conduct daily and weekly searches for bat fatalities at the Meyersdale (PA) and the Mountaineer (Backbone Mountain, WV) wind energy sites during the six-week period corresponding with fall bat migration. In addition to gathering the fatality data needed for estimating mortality rates, our objectives were to:

- compare the precision and accuracy of intensive (daily) v. weekly searches;
- identify potential biases and determine searcher efficiency and scavenging/carass removal rates;
- develop recommendations for improving and standardizing fatality search protocols; and,
- associate fatality location and timing to turbine and environmental characteristics.

Potential Biases

There are several types of potential biases that may occur when estimating fatality rates, and I discuss at least two of them. The first is that dead or fatally injured bats may land or move *outside* the search area. This bias has often been ignored when there has been reason to believe the number of carcasses outside the plot represents a small percentage of the total. The alternative approach is to estimate the percentage of fatalities that fall (or move) outside the search area.

In a forested area, the size and shape of the search area is limited to the cleared area around the base of the turbine. (It would not be worthwhile to try to search the still-forested area, because searcher efficiency would be too low.) At the Stateline wind project (OR/WA), where the fairly open terrain permits us to check how many fatalities show up outside the immediate turbine area, most fatalities can be found within 40 m of the turbine base. At Mountaineer, because the forested edge is in some cases within 30 m of the turbines, estimating the bias is important. We have not estimated this bias yet, but will do so based on the distribution of fatalities as a function of distance from turbines in searched areas.

The second type of bias has to do with how well we are able to determine scavenging rates. There are several possible problems with the use of trial carcasses to represent actual wind turbine casualties. One potential bias could result from putting out so many trial carcasses that you start attracting scavengers. (Some scavengers may even be attracted by the sight (or scent) of people placing the carcasses.) Small bird carcasses are easier to obtain than bat carcasses, but may not necessarily provide accurate information about the rate at which bat carcasses are scavenged. Frozen carcasses may not be scavenged at the same rate as fresh carcasses. Carcasses identified during scheduled searches were either left in place or in some cases re-located for purposes of testing scavenger removal rates.

Plot/Transect Design and Fatality Recording

Search plots were defined as 130 m x 120 m rectangles around the base of the turbine. Actual plot boundaries were defined by the forested edge or other unsearchable habitats (e.g., tall brush piles). Habitat within the search plot was then delineated on the basis of predominant cover type: bare ground, short, medium, or tall vegetation, large rocks/boulders, piled brush. Areas that can be searched are rated using a "visibility index" indicative of the likelihood of a searcher finding a carcass in the type of cover predominating.

Transects are oriented north-south, 10 m apart (13 per plot). Observers walk each transect, recording the date, time and location of each fatality found, the observer's distance from the carcass at the time of first detection, distance from the carcass to the nearest point on the transect line, and information about the predominant cover type and visibility of the carcass. Observers photograph most of the carcasses, assign them identification numbers, and record information about their species, age, sex and condition (i.e., evidence of scavenging, injuries, estimated time of death). Fresh carcasses are used for carcass removal trials.

Searcher Efficiency Testing

Searcher efficiency was tested using both human observers and dogs working with human observers. (In the latter case, the human is primarily observing the behavior of the dog, not looking for carcasses.) Searchers were unaware of testing. Carcasses in various conditions (fresh, desiccated, scavenged) were distributed randomly throughout the study period and throughout the study plots, under various weather conditions and in various habitat types. Searcher efficiency rates were very different at the Meyersdale and Mountaineer sites.

Scavenging and Carcass Removal Trials

Carcasses found during fatality searches were subsequently used (either in situ or elsewhere in the search plot) to determine scavenger removal rates. Some frozen carcasses were also used. Attempts to avoid attracting scavengers included placing the carcasses before daylight and using gloves and boots to avoid imparting human smell that might attract scavengers to the carcasses.

Analysis of Data

Adjusted fatality rates are calculated as the observed per-turbine fatality rate divided by the estimated average probability a carcass is available during a search and is found. The denominator in this formula is a function of carcass removal, searcher efficiency, interval between searches, search area visibility index, etc. This analysis is still being completed, and will be subject to peer review before it is released. Other analyses to be completed will include correlations of fatality metrics with environmental and turbine characteristics, e.g., wind speed, turbine rpm, lighting, etc.

Preliminary Fatality Results: Meyersdale Wind Energy Facility

presented by
Wally Erickson, WEST, Inc.

The Meyersdale Wind Energy Facility is located in southern Pennsylvania, approximately 50-60 miles northeast of the Mountaineer (WV) site. The site, which became operational in December 2003, consists of 20 1.5-MW turbines, 116 m maximum height at blade tip, with rotor blades 35 m in length (for a rotor diameter of 70 m). Six of the turbines are fit with red strobe lights on the nacelle. The facility is situated on a forested ridge top which has been cleared for the turbines.

Working with two full-time and two part-time technicians, the research team set up a search schedule which involved conducting fatality searches at all 20 turbines every Monday over the six-week study period. Half the turbines were also searched on a daily basis, with odd-numbered turbines searched daily during the first three weeks, and even-numbered turbines searched daily during the second three weeks.

Bat Fatality Results

Every one of the 20 turbines had at least three bat fatalities over the six-week period. The mean observed fatality rate was 13.1 fatalities per turbine. Approximately 300 bat fatalities were identified, including nine fatalities found during the three-day set-up period (July 30-Aug. 1), 262 found during scheduled search days, and 19 incidental fatalities. Incidentally

identified fatalities were collected (for species identification purposes) or left in field to see if they were scavenged or identified during a subsequent search.

Searchers estimated the approximate time of death. About half of the fatalities found were estimated as having occurred the night before. Based on fresh fatality finds only, the timing of red bat and hoary bat fatalities appear to be highly correlated. We also found a high correlation in the timing of fresh fatalities between fatalities found at Meyersdale and those found at the Mountaineer site.

Preliminary data suggest that lighting on wind turbines was not attracting bats.

Searcher Efficiency

Approximately 200 trial carcasses (both fresh and decomposed) were used to test searcher efficiency at Meyersdale. Overall, searchers identified 25% of the test carcasses, based on a single day's search; higher detection rates were achieved with multiple searches. In a limited (6-day) trial, humans working with trained search dogs did 2-4 times better on average than human observers working without dogs. (Dog-human search teams achieved 71% searcher efficiency at Meyersdale, as compared with 25% overall for human searchers.) In areas with low visibility habitats, dog-human teams were more than four times as effective as humans working alone.

Carcass Removal Trials

Carcass removal rates were extremely low at Meyersdale. Approximately 140 bat carcasses were used to test carcass removal/scavenging rates. Most of these were fresh carcasses, left where they had been found during fatality searches. Some of the bats found by searchers were moved to less visible locations and subsequently monitored for scavenging. Some previously frozen carcasses were also used. Approximately 5% of trial carcasses were removed within 24 hours of placement. ("Removed" means technician who placed the carcass couldn't find it on a subsequent day.) Only 20% of carcasses were removed within 16 days of placement. Because the carcass removal rate was so low at Meyersdale, daily searches yielded only 2.1 times the number of bat fatalities as weekly searches, despite having seven times the search effort. (This is a very site-specific result, as carcass removal rates vary considerably from one site to another. At Mountaineer, for example, scavenging rates were noticeably higher.)

Next Steps

- We need to adjust fatality estimates for searcher efficiency, carcass removal, search area, and habitat to yield estimates of site mortality rates. This data still needs to be written up and peer-reviewed.
- Our recommendations for study design include using carcass removal rates in selecting search intervals, and possibly moving toward intensive searches at a small number of turbines, less intensive searches at a wider sample of turbines. Final recommendations will be included in the final report.
- We saw a negative correlation of fatalities with wind speed, plotting fatalities against

average wind speed from nine p.m. to six a.m. It may be that bats are less active on windier nights. We will need to look at other weather factors (fronts) as well as wind speed and other factors to better understand what's going on here. Correlation of fatality timing with environmental factors may be useful in coming up with solutions.

Preliminary Fatality Results – Mountaineer Wind Energy Center, WV

presented by
Jessica Kerns, University of Maryland

The Mountaineer Wind Energy Center is located at an elevation of 1,025 m. on Backbone Mountain in West Virginia. The site began operation in December of 2002, and consists of 44 1.5-MW turbines and two meteorology towers. The turbines are 116 m tall, with blades rotating at 17 rpm. Twelve of the turbines (every 3-4 turbines) are lit with FAA-recommended L-864 red strobe lights. The site is primarily linear along the ridge, with a slight curve at the southern end of string. A highway cuts across the ridge at approximately the middle of the turbine string.

During the first year post-construction (2003), a survey was conducted that consisted of weekly searches (in concentric circles up to 60 m from turbine base) during the spring and fall, and monthly searches during the summer. Results were adjusted based on a single removal/searcher efficiency trial conducted in October. The mean number of bird fatalities for the entire study period (April 4-November 11) was 4.04 per turbine (4.8 birds per turbine with the addition of a single fatality event in May). During the same period, a total of 2,092 bat fatalities – and average of 47.53 bats per turbine – were identified.

The 2004 study effort followed the same protocol used at Meyersdale (see above). Six full-time technicians were devoted to the 6-week effort, from July 31 to September 11, 2004. All of the turbines were searched on Saturday, while half of the turbines were searched four days a week. (Odd-numbered turbines were searched more intensively during the first half of the study period; even-numbered turbines were searched more intensively during the second half.) Depending on the searchable area around the base of the turbine and the type of habitat, searchers spent 30-90 minutes at each turbine.

Fatality Results

A total of 456 bats were found during the six-week period, 398 found during searches, and 68 found incidentally. (Incidental finds include fatalities found after a search, at an unsearched turbine, and carcasses seen on the road but scavenged prior to the next scheduled search.) During the same period, a total of 15 bird carcasses were found (12 during scheduled searches, another 3 incidental finds).¹

¹One of the bird fatalities was a raptor, one a vulture; the rest were passerines.

One question raised by last year's study was whether the size of the area searched determined fatality findings. Comparing the distribution of bat fatalities by turbine with the area searched around each turbine suggests this isn't the case. There is only a weak positive correlation ($r = 0.2$) between the total amount of area searched and the number of bat fatalities found. In open habitat where the likelihood of carcass detection is higher, there is actually a weak negative correlation ($r = -0.2$) between size of area searched and number of fatalities found. It may be that scavenging rates are higher in higher-visibility habitat.

One turbine (# 11) was freewheeling – essentially not moving. No fatalities were found at this location.

Ninety-three percent of the fatalities were found within 40 m of the turbines, with only 1.5% found more than 50 m away. A somewhat higher distribution of fatalities was found to the east of turbines, possibly because the service road running along the ridge to the east of the turbine string made it easier to find those fatalities. A distribution of bat fatalities by species was also plotted, with hoary bats being found a mean distance of 24.6 m from the nearest turbine, red bats 23.5 m, and Eastern pipistrelle's an average of 21.8 m away.

Timing is critical at Mountaineer. Hoary and red bat fatalities are temporally correlated. Pipistrelle fatalities were spread fairly evenly throughout the study period. These three species represent the bulk of the fatalities found. Brown bat and silver bat fatalities occurred in periodic fluxes. There were two spikes in overall fatality levels, one in early August and the second in early September. The first was during a period of low wind, with turbines hardly turning; the second followed a weather front. It will be interesting to see how these spikes relate to weather conditions.

Fatalities are mostly adults, and include far more males than females. Male and female bat fatalities appear to be correlated temporally. Thirty-five percent of the fatalities showed no visible injuries; 25% had wing injuries; 10% had suffered lacerations, and 8% had both a wing injury and one or more other injury. A quarter of the fatalities found could not be assessed due to the condition of the carcass.

As at Meyersdale, no difference was detected in the rate of fatalities at lit v. unlit turbines. Likewise, it doesn't appear to be the case that anemometer operation affects mortality. Site anemometers were turned off from August 26 to September 11, and fatalities continued to occur at turbines with non-operating anemometers.

Searcher Efficiency

Searcher efficiency was higher than expected, 43.6% overall. However, efficiency varies greatly by habitat type, from over 60% in high-visibility habitat to less than 10% in extremely low-visibility habitat (brush, tall grass). Distance from transect lines was also a factor. (The highest find rate was actually 2-3 m from the transect line.)

Carcass Removal

Carcass removal is a big factor at the Mountaineer site. Overall, 328 bat carcasses were tracked for removal, including 255 carcasses randomly distributed throughout the study area (under various weather conditions and in various habitat types). Searcher-identified carcasses were left where they were found and subsequently tracked for scavenging removal rates. (However, if searchers happened to see these carcasses, scavengers are also likely to see them, so these may have been scavenged at a higher rate.) Corvids (ravens) especially were a big factor in carcass removal. These birds learn quickly; it may be that we will see more scavenging at Meyersville during the second year of operation.

Of the randomly distributed carcasses, 35% are gone within 24 hours, and 68% gone within 3 days. Of the incidental finds, 25% gone in the first 9 hours. Bat carcasses in the road, 40% removed that morning, 87% removed within 24 hours.

There is a faster removal rate of fresh carcasses compared to frozen carcasses, especially during the first few days. A total of 56 bird carcasses were also tracked for scavenging/removal. Two of these were found carcasses; the rest were sparrows, pigeons, and a few smaller passerines randomly distributed throughout the study site. Only 14% of bird carcasses were removed after 24 hours, 43% removed within three days. It should also be noted that bats disappear more completely than birds (no feather spots).

Key Points

- Fatalities at Mountaineer are comprised of 6-7 bat species, none of them endangered. (No Indiana bats found.)
- Timing of fatalities is correlated at the Mountaineer and Meyersdale sites.
- Weather is a factor; mortality is lower on nights with higher wind speeds.
- Fatalities were fairly evenly distributed throughout the turbine string, independent of lighting, anemometer operation, and amount/size of area searched.
- Carcass removal may be a learned activity, which might account for higher scavenging rates observed at Mountaineer (now in its second year of operation) and Meyersdale.

Next Steps

We now need to adjust our fatality estimates for searcher efficiency, search area, and scavenger removal biases, and incorporate habitat into our modeling. We will need to evaluate daily v weekly search intervals, and correlate the timing of fatalities with weather and turbine operation characteristics. The findings presented here are limited to a six-week study period, and are not representative of all bat activity. We will need more information to begin developing deterrents.

Preliminary Comparison of Nocturnal Passage Rates and Bat Fatalities in Pennsylvania and West Virginia

presented by
Brian Cooper, ABR, Inc.

One hypothesis offered to explain the high number of bat fatalities found at the Mountaineer wind energy facility in 2003 is that they may have been related to high levels of bat activity. We collected pilot data to begin to investigate this possibility by looking at nocturnal passage rates between Aug 10 and Aug 14 at the Mountaineer site. Between August 15 and September 13, we also made opportunistic comparisons of fatality rates at the Meyersdale wind energy site in southern Pennsylvania with nocturnal passage rates over Casselman (about 25 km to the west) and Martindale (about 75 km to the north).²

Methodology

We used a combination of radar and visual data to calculate passage rates at or below turbine heights. Mobile radar was used in surveillance mode to determine flight direction and passage rates. We alternated between (horizontal) surveillance mode and vertical mode, which was used to determine flight altitudes. Bats cannot be distinguished from birds using radar data alone. Visual observation using night vision goggles and filtered spotlights enabled us to make this distinction, and these tools give us a greater range than ultrasonic technology. We conducted daily searches (discussed in the preceding two talks) to pick up the fatalities.

Findings

Through visual techniques, we determined that there was a higher proportion of bats to birds early in the study period (Aug 10-20). The proportion of birds to bats grew as bird migration intensity increased later in the study period.

Passage rates were defined as the number of bat targets per kilometer per hour within turbine height. At Mountaineer we were able to get only three days' worth of data due to rainy weather. This small sample at Mountaineer was suggestive of a correlation between passage rates and fatalities, but the data set is too small to draw any conclusions.

No correlation was found between passage rates at Martindale and Casselman and the fatality index at Meyersdale, although there were sources of variation in the data that were not addressed in this analysis. Briefly:

² The question was raised why passage rates were not collected at the Meyersdale site itself. The Meyersdale study was not originally designed to include passage rate data collection; B. Cooper happened to be collecting data in the area of Martindale and Casselman at the time the fatality searches were being conducted at Meyersdale. Given the proximity of those sites to Meyersdale, researchers took advantage of the opportunity to look for any correlations. It was noted that B. Cooper donated his time to conduct and synthesize this research.

- Passage rates and fatality data were not collected at same sites. Casselman is 25 km due west of Meyersdale; Martindale is 75 km away, to the north and slightly east of the wind site at Meyersdale.
- There was an apparent time lag between fatalities and passages that could have resulted from difficulties in determining how fresh the fatalities were (fatality rates were based only on "fresh" carcasses).
- Bat passage rates included all species of bats, not just those prevalent in fatality data.
- The Casselman and Martindale ridges are not highly linear as the Meyersdale ridge is.

Research Needs

Preliminary results of this pilot study are inconclusive regarding the correlation between passage rates and bat fatalities. This was an opportunity to collect a very limited data set in the hope of illuminating something about a possible relationship, but clearly, more study is needed. To conduct a more rigorous analysis, we recommend collecting concurrent radar and fatality data from the same facilities for whole seasons. We also need to develop ways to refine bat passage rate measurements to focus on those species at risk of fatalities.

The correlation between fatality rates at Mountaineer and Meyersdale (see Erickson and Kerns presentations, above) suggests that fatality rates may be associated with regional environmental factors. More study is needed to determine what these factors are (if they exist), and whether passage rates are affected by similar factors.

Bats and Wind Turbines: infrared analysis of abundance, flight patterns and avoidance behavior

presented by
Jason Horn, Boston University and BCI

This presentation summarized findings from an infrared (thermal imaging) analysis of bat abundance and flight patterns in the vicinity of wind turbines at the Mountaineer wind energy site at Backbone Mountain, WV. While we can make hypotheses about what is happening in the air, we don't have any visual observations of how bats are actually getting killed. Are bats attracted to some physical attribute of the turbines, such as ultrasonic noise or the motion of the blades? To increased prey density? Or are fatalities merely random events: a case of bats being in the wrong place at the wrong time?

This study was designed to observe bats among the turbines. Our aim was not only to document mortality events, but also to characterize behavior, look for evidence of attraction, test the effect of blade rotation, and also the impact of lighting.

Methodology

We used FLIR S60 thermal infrared thermography to produce digital radiometric data. Each pixel represents a temperature value. (See Tom Kunz' presentation in Session V for a

more detailed description of this technology and its application.) For each turbine, we filmed at a 50-degree angle from the ground, using three cameras with 45-degree field-of-view (FOV) lenses, to look at the left, right and lower portions of the rotor swept area. Each camera recorded 15 GB per hour of data, requiring 45 250-GB drives to store the information.

We spent a total of 20 nights filming. Half of those nights were spent filming lit turbines, the other half the time at unlit turbines. Observations were coordinated with ground fatality searches.

Object Classification

The following criteria are used to distinguish bats from insects and birds. While both birds and bats have a visible fast wing beat frequency, birds exhibit constant velocity and high inertia. Bats, by contrast, exhibit variable attitude and/or velocity, and pursuit maneuvers. Insects have low inertia, appear fainter because they are not warm, and can only be seen when they are flying low, beneath the camera's focal plane.

Behavioral Observations

For each object observed, we recorded the time; the type of object (bat, bird, insect, or unknown); its orientation and heading while entering and exiting the frame; its perceived distance (low, medium, high); and the type of behavior exhibited.

Avoiding the blade. Real time video clips show a bat appearing to avoid the turbine blade. While we can't tell from the clip exactly how far the bat is from the blade, it seems (based on the size) to be somewhere in the plane of the blade. (In some cases we noted avoidance near the blades' tips, in other cases near the hub.) Note that the bat's course and velocity are changing, as the bat appears to avoid the blade and continue to fly.

Contact with blades. Other video clips show what appear to be glancing blows, indicated by an abrupt change in the bat's attitude and velocity. The bat changes course at the point where bat and blade meet, and the bat appears to tumble, rather than continue to fly.

Investigative behavior. One of the behaviors we noticed was what we describe as "investigative" behavior – bats circling within rotor swept area, or near hub of the turbine. This sort of investigative behavior is typical. When bats alight or roost, they often make several "check" passes first to investigate the object before landing.

Buffeting. Apart from avoidance, it appears that bats flying within the range of the turbine rotor are buffeted by turbulence from blade.

Flight patterns. One case where three bats move through the rotor swept area together on same flight pattern is atypical; bats do not typically follow the same flight patterns.

Preliminary Analysis

Given the sheer quantity of the data (8 TB of digital radiometric data over a 20-night period), it is extremely time-consuming to analyze. For example, we have begun comparing bat passage rates with mean sky temperature to see whether there is a relationship between weather and bat activity, but we've only been able to look at three nights' worth of data so far. Some of our preliminary conclusions are:

- Most activity takes place within the first few hours after dusk.
- Individuals often fly through the rotor-swept area, apparently "investigating" both moving and non-moving blades.
- Bats seem to be able to avoid moving blades, and the ratio of avoidance to contact is high. (Again, however, only a small portion of the data has been analyzed so far.)
- Activity level is highly variable across nights.

Next Steps

As we complete our analysis of this data, some of the things we will be looking for will include: an analysis of orientation and wind direction; whether the rate of bat activity varies with turbine rotation and orientation; and, whether bats appear to be attracted to lit v. unlit turbines.

Wrap-up: Current Knowledge and Next Steps

presented by
Merlin Tuttle, Bat Conservation International

[Panel moderator acknowledged] a "Herculean effort" on the part of Ed Arnett, Wally Erickson, Jessica Kerns, and Jason Horn and their co-workers for resolving research issues and "contributing a tremendous amount" to the knowledge base on very short notice. "When we met [in Florida] last February we were almost paralyzed for lack of data to look at. I've never seen any project that did better at resolving more issues faster than this group." This year's accomplishments have included:

- Testing sampling protocols and improving estimates of searcher efficiency and scavenging bias in varied habitats
- Assessing the effectiveness of different methods and technologies
- Obtaining, for the first time, a data set that will allow us to correlate mortality with weather, turbine activity, and other risk factors.

It is important to keep in mind that the findings presented here represent a very rough preliminary analysis of data just recently gathered. When analysis of the 2004 data set is

completed, we should be able to:

- Recommend standardized mortality assessment protocols and procedures
- Develop experiments to further test habitat, weather, turbine, and topography-related risk factors
- Begin experimentally testing potential solutions

Clearly, we cannot assume little or no risk to bats on the basis of what we've found in studies designed to detect bird fatalities. A lot of work remains to be done to find out the reality for bats. To date, most studies on bats have come from open prairie and croplands where bat mortality appears to be lowest. We're seeing something very different in forested areas, so it's clear that we cannot extrapolate from the open sites to the forested sites. Wooded areas do seem to raise the risk to bats. Likewise, we cannot assume that there is not a problem for bats in the West simply because we have not seen it at a few open prairie/cropland sites. Very little has been studied. Very different bat species inhabit the South and Southwest, and their behavior and mortality may be very different. (For example, the Mexican free-tailed bat forages in the kinds of open areas where we have tended to find fewer fatalities of more northern bat species in the West.)

Given the estimated number of bats killed per turbine at Mountaineer in 2003 and plans to build at least 366 more turbines in the immediate vicinity, the potential for bat fatalities is alarming. This highlights the urgency of collaborating to find solutions as quickly as possible.

Next steps

We need to document mortality from spring through fall, looking at the potential for cumulative impacts.

Comparative data on the magnitude and predictability of fatality events under varied topographic and habitat conditions could help with pre-project risk assessment and project design.

Finally, we need to begin testing measures that may help prevent or mitigate impacts, including: alteration of turbine sounds and surfaces to repel or at least avoid attracting bats; and the cost-effectiveness and conservation impact of feathering turbine blades during periods of peak risk.

23		

1 MR. FIDICH: We're going to call the
2 meeting to order. It's 7:08. I'm going to
3 turn the table over to Dave Copeland. He's the
4 one that's going to be running the meeting
5 tonight

6 MR. COPELAND: Hello everyone. Can you
7 all hear me? The room definitely acoustically
8 has an edge to it. And we have a lot of people
9 here. I appreciate everyone coming down
10 tonight. Going to go over a couple of things
11 here.

12 First, before we go ahead and get started
13 with the public hearing, one of the things I do
14 want to explain in regards to what's going to
15 be occurring tonight is tonight is a public
16 hearing. It's not a question-and-answer
17 period. And I've been to a lot of the other
18 town board meetings that have been very --
19 great board meetings with a lot of feedback
20 going back and forth on these projects; been
21 able to exchange a lot of concerns and get
22 information back.

23 Unfortunately to stay within the realm of

1 what we need to do for the SEQRA process of
2 doing the Draft Environmental Impact Statement
3 and ultimately the Final Environmental Impact
4 Statement this is going to be in the context of
5 a hearing, not questions/answers, back and
6 forth. So if your bringing up questions, those
7 will be put into the notes and then those
8 questions will be then addressed in writing as
9 part of the Final Environmental Impact
10 Statement.

11 One of the things I need to do is just
12 sort of read off the Public Notice that I'm
13 sure a lot of you have seen in the paper. You
14 know, it says:

15 The Town of Clinton, Clinton County,
16 Notice of Joint Public Hearing on Draft
17 Environmental Impact Statement and Wind Energy
18 Permit Applications. Noble Clinton Windpark,
19 LLC Application, Marble River, LLC Windfarm
20 Application.

21 Notice is hereby given that the Town
22 Board of the Town of Clinton will hold a public
23 hearing at 7:00 p.m. on May 25th, 2006, at the

1 Churubusco Fire Hall, Churubusco, New York, to
2 receive comments on the (1) applications for
3 the wind energy permits (2) the Draft
4 Environmental Impact Statements (DEISs)
5 submitted by Noble Clinton Windpark, LLC and
6 Marble River, LLC for the constructions and
7 operation of the Wind Energy Generating
8 Facilities and related infrastructure (electric
9 lines, access road, substation) in the town.
10 The Town Board of the Town of Clinton acting as
11 lead agency under State Environmental Quality
12 Review Act had determined that the Noble
13 Clinton Windpark, LLC and Marble River, LLC
14 projects could have a significant adverse
15 impact on the environment and therefore issues
16 a positive declaration and ordered each
17 applicant to prepare a DEIS for their project.
18 The hearing are being held jointly so the Town
19 Board can receive comments on all cumulative
20 impacts on the project. The respective
21 application and DEISs are available for review
22 at the Town Clerk's Office Churubusco, New
23 York.

1 At the time set above all members of the
2 public will be heard. In addition, written
3 comment can be submitted to the Town board
4 until June 5, 2006 at Town Hall, Chaturbusco,
5 New York.

6 I'm just going to go over and discuss a
7 couple of rules for the public meeting. You
8 know, if you wish to speak at the public
9 hearing, you know, sign in on the speaker list.
10 Currently, we have the updated list up front.
11 There's also another list in the back. So if
12 you want to speak, please go on the list.

13 At the very end when all the people that
14 are on the list are done giving their
15 statement, we will open it up if anyone else
16 wants to come on up and add something else to
17 the public hearing.

18 The purpose of the meeting is to hear
19 comments from all the members of the public.
20 You know, this is not a question-and-answer
21 session, nor is it a debate. Comments may be
22 addressed to any aspect of the application and
23 the DEIS. This is the appropriate forum to

1 give the Town Board your opinion of whether the
2 application should be approved, approved with
3 conditions, or disapproved. It's also
4 appropriate to comment on any aspect of the
5 DEIS including asking any questions that you
6 feel were not resolved in the DEIS.

7 In order to allow everyone to be heard,
8 please limit your comments to four minutes.
9 Tom is going to be keeping the stop watch.
10 When you begin approaching the four minutes,
11 we're going to flag you and let you know you
12 have about 30 seconds to go. Please stay
13 within that limit.

14 If you're representing four or five or
15 more people, and those five or more people are
16 physically present here tonight, you'll be
17 allowed up to 10 minutes. If you do come up
18 and you're going to make that claim, we will be
19 needing to get the names of the five people
20 you're representing.

21 A real important item here, you know, I
22 know this is a very controversial issue for a
23 lot of folks here, but please show respect for

1 the person coming up and giving their talk.
2 You know, we -- this can very easily become
3 very difficult to hear with the echo and
4 everything. Please allow everyone that does
5 come up to speak the courtesy to be heard, so
6 that they can, you know, feel that they are
7 part of the process.

8 I'm going to ask that you minimize
9 talking. You know no comments or anything
10 else. Just let people please make the talk.
11 If you want to clap at the end, that's fine,
12 but I'm also going to request no booing or
13 anything. I want to keep it on a positive
14 note. Keep it in mind that you're all
15 neighbors here in the community. Regardless of
16 what people's positions are on the subject
17 matter, we're all neighbors. So let's make
18 sure we keep respect for everyone

19 When do you come up to the front, please
20 state your name and address.

21 Is there any questions in regards to the
22 rules of the meeting?

23 I forgot number five. If you have

1 written comments, please submit them to the
2 board rather than reading them. All written
3 comments will be part of the record. Written
4 comments will be accepted until June 5, 2006.
5 You know you can send them either to The Wind
6 Project Comment, the Town Board or to Daniel
7 Spitzer who is the town attorney.

8 So with that, we'll go through the list.
9 Based on my experience at Killburg last night
10 I'll come right out and tell you I'll
11 mispronounce many names and I apologize ahead
12 of time. You know I'm one of those guys, give
13 me a good long name and I'll do fine. You give
14 me the name of Smith and I'll find a way to
15 goof it up, so I apologize about that ahead of
16 time.

17 The first person on the list is Mike.

18 MR. FILON: My name is Michael Filion
19 726 Route 11, Churubusco, Town Supervisor. All
20 I wanted to do is put in the record that so far
21 we have received 13 letters that's in favor and
22 also 52 postcards in favor. And one against
23 and one had questions and concerns about the

165

1 DBIS. So as of that, I'll turn it over and let
2 everybody speak.

3 MR. COPELAND: Thank you.

4 The next person is Cassandra Burl.

5 MS. BURL: I wrote mine out.

6 MR. LEVY: Cassandra Burl submitted a
7 letter.

8 MR. COPELAND: The next person is Kirby
9 Selkirk.

10 MR. SELKIRK: You did better than last
11 night.

12 My name is Kirby Selkirk. I live in
13 Chateaugay. I'm a field advisor for New York
14 Farm Bureau and I'm here on behalf of Clinton
15 County Farm Bureau and several of its members
16 that live in the area. I'd like to submit to
17 the hearing a statement of resolution that
18 Clinton County Farm Bureau passed on May 11th,
19 2006, in support of the establishment of
20 commercial wind turbines on its members' farms.

21 I would also like to submit copy of a
22 narrative of information that we have compiled
23 supporting that I would also like to submit

Burnham Reporting (315) 379-0205

166

167

167.1

167.2

1 policies that the New York Farm Bureau has on
2 the siting of energy facilities and
3 agricultural land not the least of which is a
4 request that the New York State Department of
5 Ag and Markets be included in all of the
6 regulations, be included -- the regulation
7 insist that the New York State Department of Ag
8 and Markets be included in regulations
9 governing construction and in talking to some
10 of the folks at Noble, I know they are.

167.2

11 And lastly, I received from New York Farm
12 Bureau today a copy of a Study of Impacts of
13 Windmill Visibility on Property Values in
14 Madison County, New York.

15 But quick in summarizing, the results of
16 the report finds no measurable effects of
17 windmill visibility on property values. One
18 other part of the sentence, further the report
19 offers the possibility that affects are more
20 myth than reality.

167.3

21 I'd like to submit these to your hearing.

22 MR. COPPELAND: Okay. Thank you. I'm
23 having a -- is there a Roger Cronsted? I'm

1 having trouble reading the writing here.

2 MR. FILION: It's a long last name.

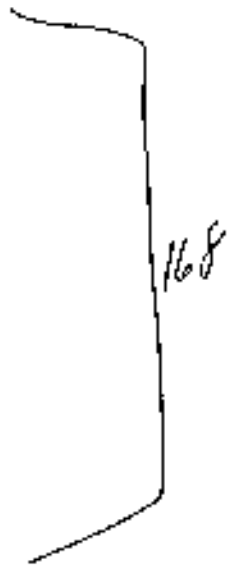

3 MR. LEVY: Where is he from?

4 MR. FILION: Roger from Keeseville? Is
5 there a Roger from Keeseville that signed the
6 speakers' list -- that occurred on the list?

7 MR. COPPLAND: Okay. Norbert Kainzler.

8 MR. KAINZLER: I'm Norbert Kainzler. My
9 mailing address is 34 Ryan Road, Chateaugay,
10 New York. However I'm a residence of Ellenburg
11 Town. My land borders the Town of Clinton so I
12 would like to say a few words to the Clinton
13 Town Board.

14 First off, I support the construction of
15 the wind projects. I think they will benefit
16 the community and the individuals. We've
17 already seen an economic impact. One company
18 has setup an office in Churubusco. The other
19 company has setup an office in Ellenburg.
20 They've hired local people and they have spent
21 considerable money here, fuel, food, and so
22 forth. I think that the projects, when
23 completed, will be good not only for us, but

1 the entire world, since it will reduce
2 greenhouse gas emissions to produce
3 electricity. Thank you.

4 MR. COPELAND: The next person is Dan
5 Haas.

6 MR. HAAS: My name is Dan Haas. I'm
7 managing director of Noble Environmental Power.
8 I'm responsible for the engineering,
9 construction, and operations of all of our
10 facilities. I was born and raised in Hudson
11 Falls, New York. My degree is from SUNY
12 Canton. I've been a New Yorker for many years
13 of my life and I'm happy to be back here hoping
14 to change the energy mix in the state of New
15 York.

16 What I would like to enter into the
17 record today is a report that was published
18 just this month within the last couple of weeks
19 by the Utility Wind Integration Group. That is
20 a utility industry group that has gone together
21 to study the impacts of wind facilities in the
22 United States power grid. The Utility
23 Integration Group is supported in this report

169

1 by the American Public Power Association, the
2 Edison Electric Institute and the National
3 Rural Electric Cooperative Association. The
4 reason I read those three names is those three
5 associations represent virtually 100% of the
6 utilities doing business in the United States
7 today. They have endorsed this report. I
8 would like to read a few bulletin points from
9 the report and then I'll submit the full study
10 into the record.

11 First, in many cases customer payments
12 for electricity can be decreased when wind is
13 added in the system, because the operating cost
14 increases can be offset by savings from
15 displacing fossil fuel generation.

16 Additionally, further there is evidence
17 that with new equipment designs and proper
18 plant engineering systems stability and
19 response to a major plant or line outage can be
20 improved by the addition of wind generation.

21 System stability studies have shown that
22 modern wind plants equipped with power
23 electronic controls and dynamic voltage support

169

1 capability can improve system performance by
2 damping power swings and supporting post fault
3 voltage recovery.

4 A whole bunch of big engineering words
5 that boil down to say wind projects help to
6 stabilize the grid. They are a very positive
7 stability influence as part of the grid mix

8 Additionally, because of spatial
9 variations of wind from turbine to turbine in a
10 wind plant and to a greater degree from plant
11 to plant, a sudden loss of all wind power on a
12 system simultaneously due to a loss of wind is
13 not a credible event.

14 Again, a bunch of big words. If you
15 watch the wind blow across a field you'll see
16 it make waves as it moves across the grass.
17 You can see that the wind comes across a field.
18 As it moves across a field of wind turbines it
19 levels out the production. As large wind
20 movements travel across the land from plant to
21 plant as these are spread out across New York,
22 it levelizes the amount of wind energy
23 produced. That's all those big fancy words

169

1 said.

2 MR. LEVY: Thirty seconds.

3 MR. HAAS: Yes, sir.

4 Primary value lies in its ability to
5 displace energy produced from the combustion of
6 fossil fuels and to serve as a hedge against
7 fuel price risk and future restrictions on
8 emissions.

9 The addition of a wind plant to a power
10 system does not, I emphasize, does not require
11 the addition of any back up conventional
12 generation since wind is used as an energy
13 resource. Commercially available wind
14 forecasting capability can reduce the cost
15 associated with day ahead uncertainty
16 substantially. In one major study state of the
17 art forecasting was shown to provide 80% of the
18 benefits that would result from perfect
19 forecasting.

20 MR. LEVY: Time is up.

21 MR. HAAS: I'll submit the full report
22 now.

23 MR. COPELAND: Thank you. Next on the

1 list is June Britton.

2 MS. BRITTON : My name is June Britton
3 from Brandon, New York. We oppose windfarms.
4 Noble Environmental's DEIS has been reviewed
5 and should not be accepted by the lead agency,
6 Clinton Town Board, because it fails to
7 demonstrate that due concern has been given to
8 protecting the public health and safety or to
9 protecting the existing environment, natural
10 and human, of Clinton. Specific areas of
11 inadequacy, either in data presented or in use
12 of the data in meaningful ways to ensure
13 environmental and health protections are:

170

14 Assertion of public benefit of the
15 project.

16 Safety including ice throw, turbine fire
17 and seismic risk.

18 Evidence of compliance with state and
19 federal wetland laws.

20 Wildlife and game animal population
21 assessment.

22 Compliance with U.S. Fish and Wildlife
23 recommendations to the project sponsor.

170.1

1 including for multi-year, multi-season,
2 multi-weather condition bird and bat population
3 assessments.

4 Compliance with the New York State DEC
5 community noise guidelines -- not required
6 since the DEC is not the lead agency, but lack
7 of compliance shown indifference to reasonable
8 noise standards as established by our state.

9 Quality of noise assessment and modeling,
10 including the low frequency noise assessment.

11 No mitigation of shadow flicker to affect
12 the 82 homes, 50% of which are not lease
13 holders.

14 I recommend that the DEIS not be
15 accepted, and present evidence to the Town
16 Board in support of this position.

17 I'm going to ask either Mike Hilton or
18 Deborah McComb to sign to certify that you
19 received these documents from me. They are all
20 indexed on this paper.

170.2

21 MR. COPELAND: Next person is Bernice
22 Soltysik.

23 MS. SOLTYSIK: My comments are not

1 technical), but I'll read the list. I
2 understand that the willingness of the towns
3 people who favor turning the natural beautiful
4 Town of Clinton into an industrial site is
5 based strictly on money. Not from
6 understanding corporate finances, nor community
7 dynamics, nor environmental issues but just
8 what the coming of so many windmills means in
9 terms of direct payment to them and perhaps
10 some reduction in taxes.

11 However, these other realities still
12 remain, and money in hand today does not take
13 into account future impacts such as reductions
14 in value of property, the impossibility of
15 selling one's property, discouraging new and
16 younger people from moving here, abandonment of
17 the windmills when the "Big Boys" tax credits
18 run out or the utilities find the power too
19 expensive to buy from them.

20 In other words, we face the possibility
21 of a dying town. Giant windmills superimposed
22 directly on a small town is not what is meant
23 by alternative energy.

171
171.2

1 I'd like to read briefly from an article
2 of May 17th from New York Times. just a few
3 sentences.

4 "Wind power is booming and not
5 necessarily because of environmental benefits,
6 but because of the cash they spin off.
7 Earnings from wind power turn into profit
8 quickly in the first years of operation because
9 of tax breaks. Earnings from windfarms are
10 sheltered by the production tax credit. Tax
11 credit has made wind power quite 'a business
12 for the big guys'" issuing companies -- no I'm
13 sorry "favoring companies that have enough
14 cash flow to be able to use the credit. The
15 little guy doesn't have access to those big tax
16 credits.

171.3

17 In 2005 Golden Sacks crossed the line
18 from financing windfarms to owning them, buying
19 Zelka (phonetic spelling) Renewable Energy,
20 which is now Marble River.

21 Lastly an expert Rockefeller University
22 has written "The problem with wind power is
23 that to get more wind power you need to cover

171.4

1 more land which is destructive of the
2 environment."

3 MR. COPELAND: The next person is Glenn
4 Fountain.

5 MR. FOUNTAIN: My name is Glenn Fountain.
6 I live in Plattsburgh, New York. I have had
7 property up here for the last 13 years. I got
8 a significant amount, a little over 400 acres.
9 And I think that the wind energy project would
10 be a benefit to the committee and everybody
11 throughout the area with the fuel prices going
12 sky high, the energy and the nonpollution for
13 our children and the grandchildren is the way
14 to go and I hope that the board makes the
15 decision to go forth with this project.

16 MR. COPELAND: The next person is Jim
17 Sacckeri.

18 MR. SACCKERI: My name is Jim Sacckeri
19 I live at 748 County Line Road. My family and
20 friends own St. Lawrence Valley Dairy Farm,
21 which is located on the County Line Road. We
22 also lease property just to the south of us and
23 is also included in this proposed project.

1 As I've said at meetings like this
 2 before, I think the wind energy project is a
 3 wonderful project. It produces clean energy
 4 helping to replace coal, helping replace other
 5 forms of energy. It will have great benefits
 6 for both the citizens of the town, land owners,
 7 the employees, businesses, schools,
 8 infrastructure, but since this meeting tonight
 9 directly involves the environmental concerns of
 10 the project I want to ask -- I feel that the
 11 board should approve the Draft Environmental
 12 Impact Statement.

13 I've witnessed the studies firsthand on a
 14 bat monitor was on our side, radar truck
 15 tracking bird migration was parked on our farm
 16 many nights. I can tell you between the people
 17 that Noble employs and also people from the
 18 State of New York the Department of Ag and
 19 Markets they literally walked every square foot
 20 of our property, and as I said, the property to
 21 the south that we lease, marked every little
 22 spot there was a wetland. I know they've done
 23 a careful study. It's taken a long time. It's

173

1 been well over a year. And I think that the
2 board should approve this project. It would be
3 a great project for our whole community.

4 MR. COPELAND: Okay. So far is there
5 anyone that I haven't called that signed up on
6 the very first list? We still have one person.

7 Dorothy Glance.

8 MS. GLANCE: Thank you for the
9 opportunity to comment. My name is Dorothy
10 Glance. I am the program director for Citizens
11 Community for the Environment. We are a
12 statewide nonpartisan nonprofit environmental
13 advocacy organization. We operate on the
14 philosophy of pollution prevention,
15 conservation, environmental sustainability.

16 And I'm here tonight, I have had a chance
17 to review the Draft Environmental Impact State
18 for Clinton, and I'm really impressed. We're
19 very strongly in support of developing
20 renewable energy recognizing the damages that
21 come from our reliance on fossil fuel from
22 increase rates of asthma, which are directly
23 tied to the emissions that are released, to

174

1 acid rain, to the damages that are caused from
2 global warming and global climate change from
3 carbon dioxide emissions, and wind energy
4 provides that answer.

} 17A

5 And what is so important is to make sure
6 that the property is sited. We strongly
7 support rigorous environmental reviews, like
8 the Draft Environmental Impact Statement, and
9 the results I think are pretty amazing.

10 Just to make sure I get everything right
11 this is going to be generating 102 megawatts of
12 clean energy and it's going to affect less than
13 150 acres. It's going to disturb 5.8 acres of
14 wetlands and only permanently impact 2.9
15 acres.

16 New York State regulations outside of the
17 Adirondack Park only recognizes wetlands of
18 12.4 acres or larger. I've been working real
19 hard to get the state to protect more wetlands.
20 This is pretty amazing to have this size of a
21 development affect you know permanently
22 affect only 2.9 acres of wetland. Noble has
23 pledged to make sure that all of the wetlands

1 that are permanently impacted are going to be
2 replaced on a 2 to 1 ratio, at least.

3 Additionally, the impact of both birds
4 and bats are not biologically significant. 276
5 birds I believe -- or 150 birds and up to 293
6 bats are expected to perish as a result of the
7 windfarm.

8 Whenever you erect any tall structure
9 whether it's a building, you're going to have
10 impacts, but you need to put it in perspective.
11 Birds and bats are very much impacted through,
12 not only bats in the community, pesticides
13 applications, but also acid rain, increased
14 mercury in the food chain. I don't know if you
15 guys are following what's going on with loons
16 right now. But they're showing signs of
17 mercury poisoning and are becoming bad parents
18 because of what mercury is doing to them, which
19 is direct by-product of coal fire burning
20 plants.

21 It's a big decision to host a windfarm in
22 your community. I believe the -- what I read
23 about the projected noise values, you know, 35

} 7A |

1 decibels is about the noise of a quiet room to
2 kind of put it in perspective and it's going to
3 be about 50 decibels at the most.

4 So it's not going to be that challenging,
5 but it is a big difference. It's going to
6 change what your landscape is going to look
7 like. You need to put it in perspective.

8 So you know over 20 years we're going to
9 displace 3 million tons of carbon dioxide, over
10 4,675 tons of nitrogen oxide and almost 12,000
11 tons of sulfur dioxide.

12 MR. LEVY: Thirty seconds.

13 MS. GLANCE: Thank you very much. So it
14 seems to me -- well, I really appreciate the
15 opportunity to express our perspective with the
16 residents of Clinton. Wind power offers
17 innumerable environmental and economic benefits
18 to local economy, the region, the state and our
19 nation as a whole. Deciding -- like I said,
20 it's a big decision to decide to host a
21 windfarm. It must be made considering all the
22 fact inclusive of all points of view. Many
23 finding sleek turbines a form of art.

1 Something that holds a promise for a better
2 future for our children. Just like other
3 example of art, we need to agree to disagree.
4 These perspectives will both valid, should not
5 be the sole determining factor of whether or
6 not you're going to decided to host a windfarm
7 in your community. Thank you very much for the
8 opportunity to comment.

9 MR. LEVY: She submitted comments on the
10 Noble Clinton Windpark.

} 174.2

11 MR. COPELAND: Has anyone signed up and
12 has not been called up yet?

13 Is there anyone additionally that would
14 like come up and say anything?

15 MR. LYONS: My name is Mark Lyons. I'm
16 the director of project development for Noble
17 Environmental Power. I just wanted to offer a
18 few things for the record in this hearing.

19 First, signatures of 55 people supporting
20 the project. Two letters in support that were
21 handed to us before the hearing. One from Mary
22 Lamb. One from Ken Lamb, citizens of
23 Charubasco in support of the Noble application.

} 175.1

1 I would also like to submit a letter from
2 Paul Moller, assistant director of Madison
3 County planning department talking about their
4 experiences with the wind projects in Madison
5 County. I'm not going to read the whole thing
6 but essentially -- I will submit it for the
7 record.

175.1

8 Mr. Moller says, "I believe that our
9 windfarms have been good for the local economy
10 and that the majority of people who live in
11 these towns are positive about the wind
12 turbines." With regard to noise he says,
13 "Unless you're trying to heard it, you probably
14 won't notice it." Regarding the wildlife and
15 domestic animals quote "I know of no negative
16 impact on animals from either windfarm in
17 Madison County."

175.2

18 Regarding health and safety issues quote
19 "In the five years that the Madison and Ferner
20 windfarms have been in operation, I know of no
21 health or safety issues associated with them."
22 Regarding property values and property taxes,
23 "There is no evidence at all that the wind

1 Turbines have lowered property values in the
2 towns of Madison or Fenner." This is the
3 record.

4 And finally with regard to property value
5 I would like to submit for the record three
6 reports that are well documented and in peer
7 review. The first is very recent, it's
8 actually a master's thesis done by a gentleman
9 by the name of Ben Hogan at Bard College called
10 Impacts of Windmill Visibility on Property
11 Values in Madison County. It's the one that
12 Mr. Selkirk referred to before, but I would
13 like to submit the entire report for the
14 record.

15 Essentially his conclusion was that
16 visibility of wind turbines in Madison County
17 had no impact on property values there.

18 A report done in 2003 by the Renewable
19 Energy Policy Project studied 10 projects
20 nationwide to determine any impact of visibility
21 of wind turbines on property values. They
22 concluded that we found that for the great
23 majority of projects property values actually

175.3

1 rose more quickly in the view shed than they
2 did in the comparable community. More over
3 values increased faster in the view shed after
4 the projects came online than it did before.
5 Finally, after projects came online values
6 increased faster in the view shed than they did
7 in the comparable community.

8 Finally a report that studied 22 wind
9 projects nationwide in Oregon in 2002 economic
10 impacts of wind power in Kitteris (phonetic
11 spelling) County. Their conclusions were that
12 views of wind turbines will not negatively
13 impact property values and wind plant
14 construction will have significant economic
15 benefit.

16 To our knowledge, these are the only
17 comprehensive studies that have been done on
18 the issue. Thank you.

19 MR. COPELAND: Okay. Thank you.

20 Is there anyone else?

21 MR. HARRIMAN: Richard Harriman, Route
22 189, Churubusco. I got a very good friend who
23 runs an accounting business down in the Capitol

175.3

176

1 District area and she was talking with a client
2 today that has some connection to Tug Hill.
3 According to that client, people down there
4 have their kids' college education paid for
5 because of the wind turbines. Bed and
6 Breakfasts are full with tourists. The economy
7 in the whole area is up and some people are
8 even doing tours of their farms with the
9 windmills on it.

10 Her opinion from what she heard from this
11 man was that it's been very good for the area.
12 No real negative effect now that they're up and
13 running. I support that we go ahead and let
14 the project go ahead. Thank you.

15 MR. COPELAND: Thank you. Any other
16 comments?

17 MR. DECLAIR: My name is Toby McClair. I
18 reside at 251 Campbell Road. My address will
19 be in the middle of these two projects.

20 I would like to ask the board to really
21 consider that southwest corner of our town
22 because just in a two mile radius where my
23 house sits I'll have 81 of these turbines. The

176

177.1

1 noise levels. I'm not good with these numbers,
 2 but I got a feeling that with 81 of them within
 3 two miles, I'm not going to say it's going to
 4 be a quite room.

5 There's a lot of people, I believe that
 6 there's a lot of questions to be answered. We
 7 hear the same spiel from just about both sides
 8 and it doesn't seem like we're getting
 9 anywhere. It's just tug and pull, tug and
 10 pull. And it's basically up to the board that
 11 is sitting right here. Those five gentleman
 12 right here is going to make a difference of this
 13 town. The village is pretty well setback from
 14 where the main part of this is going to be, but
 15 the rural part up there where we're, the
 16 Campbell Road, Ryan Road, Gonyea Road, Estenovic
 17 Road. It's just unbelievable the amount of
 18 wonderfuls that are going to be there. And I
 19 can't believe that it isn't to be going a
 20 visual impact. I can't believe it's not going
 21 to be an impact on the people in those areas,
 22 as in myself other family that are there.

23 So before you make that final decision

177.2

1 really think hard about it. Our town has never
2 been in a financial crisis from as long as I
3 remember. Why do we say we need the money as
4 much as they say we do need. One other thing
5 in the decommissioning of these windmills. It
6 states in there that it's to today's dollar.
7 If they go up tomorrow, five years from now, 10
8 years from now, is it going to be based on
9 today's dollar. Everybody's raises go up. It's
10 prepared in here at \$65 an hour for one-man
11 hour. Ten years from now \$65 probably isn't
12 going to buy a gallon of gas or a gallon of
13 milk to feed your kids.

14 I'd just like to submit the
15 decommissioning report from both facilities
16 into the record for the town to look at them
17 more in depth.

18 MR. COPELAND: Anyone else?

19 MS. FILION: My name is Amy Filion. I
20 live in Churubusco and as Toby McClair was
21 stating we're the ones that's going to be
22 suffering living in the middle of this mess. I
23 have looked over the DEIS and there's many,

177.3

1 many things in there that again is going to
2 affect people that live and going to be
3 subjected to living around them for the rest
4 of our lives that these windmills are going to
5 be up.

6 We have in the past all through these
7 areas there's been four wheelers and snowmobile
8 trails and, you know, everyone traveled through
9 them and had fun. Now that they're going to
10 try putting them up, they're not going to have
11 that anymore. They're going to be all ruined.
12 There's going to be fences around them. Nobody
13 left to enjoy the view. The quietness of going
14 down the dirt roads and everything else. I'm
15 asking the board to very, very carefully
16 consider in acting in passing this DEIS.
17 There's many flaws. The noise and flicker
18 affect. It is going to affect us because our
19 homes are in the middle of it.

20 The other situation that I see is already
21 people are selling their homes. People are not
22 going to live in the middle of this mess ;
23 would like to state to the board that I was

178.1

178.2

178.3

1 proud to be in Malone last night when they
2 passed the ordinance banning the wind turbines.
3 They said quote "If we had one person we felt
4 was going to be impacted in a negative way
5 because of these windmills..." And when I
6 showed them these pictures they were horrified
7 they knew they made the right decision by
8 banning them. I thanked that board, because
9 it's horrifying to think that I will be stuck
10 in the middle of this mess and I told them that
11 "Now that you guys have banned them, if this
12 happens in my town and I can't stop it, I'll be
13 moving to your town." And they welcomed me.

14 So again, I want to stay in my home. I
15 want my children to be raised in the home that
16 my husband built. That's not going to happen
17 if this mess happens here. Look at the mess
18 already at Dick's Country Store. If you think
19 that looks great, I don't know. Thank you.

20 MR. COPELAND: Any others?

21 MR. FOURCRE: My name is William Fourcre
22 and I live at 889 Route 189, Chateaubusco. I
23 just want to tell the board that my wife and

1 myself and my family are supporters of the
2 Marble River and Noble Wind Project. I think
3 it's a great thing. We need good clean power.
4 And I believe that this is a good way to go.
5 Thank you.

6 MR. COPELAND: Anyone else? Going once?
7 Twice? Okay with that I really appreciate
8 everyone coming. I appreciate everyone giving
9 the respects to the speakers, with this I'll
10 turn it over to Mike

11 MR. FELTON: Okay. We're going to
12 adjourn the public hearing. We have a little
13 bit of business to do for the town business.
14 You're welcome to stay. It's going to take
15 about three minutes. We're probably going to
16 take a couple minutes in between here, let
17 people leave if they want to leave. You're
18 welcome to stay for the other hearing -- at the
19 other meeting, it's just going to take us a
20 couple minutes and so the time 7:04 I need a
21 motion to go ahead and adjourn.

22 Okay. Danny, succeeded by Calvin. All
23 signify by saying aye.

1 (All said aye)

2 MR. FILION: All opposed same sign.

3 (No response)

4 MR. FILION: Motion carried.

JOINT PUBLIC HEARING ON THE APPLICATION *
 FOR WIND ENERGY GENERATING FACILITIES AND DRAFT *
 ENVIRONMENTAL IMPACT STATEMENTS FOR *
 NOBLE ELLENBURG WINDPARK, LLC. *

The above referenced matter was held May 24, 2006, in
 Ellenburg Town Hall, Ellenburg, New York, before Lisa L.
 Tennyson, Certified Shorthand Reporter, Registered Merit
 Reporter and Notary Public in and for the State of
 New York.

APPEARANCES: CONESTOGA-ROVERS & ASSOCIATES
 2371 George Urban Boulevard
 Depew, New York 14043
 David C. Copeland, PE, QEP
 Thomas Levy, B. Eng. M.A.Sc.

BOARD MEMBERS: JAMES McNEIL
 GERALD PEETS
 GARY BOMBARD
 RICHARD PEARSON
 CURTIS DECOSTE

1 MR. McNEIL: I'm going to call this
2 public hearing to order. I want you to all
3 join me for the Pledge of Allegiance. I
4 pledge allegiance to the flag of the United
5 States of America, and to the republic for
6 which it stands, one nation, under God,
7 indivisible, with liberty and justice for all.

8 At this time I'm going to turn it over to
9 our moderators, Tom Levy and Dave Copeland
10 from CRA Engineering.

11 MR. COPELAND: Hello, everyone. Can you
12 all hear me okay? Okay. Great. I'm Dave
13 Copeland with CRA. One of the first things
14 I'm just going to do is just go through the
15 public notice and just prove to you all that I
16 can read up -- we will go ahead here. Within
17 the public notice, you know, the town of
18 Ellenburg, Clinton County, notice of joint
19 public hearing on draft environmental impact
20 statements, in wind energy overlay district,
21 rezoning special use permit applications,
22 Nobel Energy Wind Park, LLC, application,
23 Muscle, LLC, Wind Farm application.

24 Notice is hereby given that the town
25 board of the town of Ellenburg will hold a

TENNYSON COURT REPORTING
Lina L. Tennyson, CSR, RMR, RFR

{518} 494-7897

1 public hearing at 7 P.M. on May 24th, 2006, at
2 the Ellenburg town hall, 106 West Hill Road,
3 Ellenburg Center, New York, to receive
4 comments on the application for the wind
5 overlay district and special use permits and,
6 two, draft environmental impact statements,
7 DEIS submitted by Noble Ellenburg Wind Park,
8 LLC, and Marble River, LLC, for the
9 construction and operation of wind
10 energy-generating facilities and related
11 infrastructure, electric lines, access roads,
12 substations in the town.

13 The town board of the town of Ellenburg
14 acts as lead agency under the State
15 Environmental Quality Review Act has
16 determined that Noble Ellenburg Wind Park,
17 LLC, and Marble River, LLC, projects could
18 have a significant adverse impact on the
19 environment and therefore issued a positive
20 declaration and ordered each applicant to
21 prepare a DTS for their project. The hearings
22 are held jointly so the town board can receive
23 comments on all cumulative impacts on the
24 projects.

25 The respective applications and DTSs are

TENNYSON COURT REPORTING
Lisa A. Tennyson, CSR, RMR, RPR

1516: 404-7897

1 available for review at the Town Hall 106 West
2 Hill Road, Ellenburg Center, New York, or on
3 the Internet at
4 [HTTP://www.noblepower.com/ourprojects/ellenburg](http://www.noblepower.com/ourprojects/ellenburg),
5 Ellenburg DLE for Noble, and
6 www.marbleriverwoodfarm.com/documents/HTMLforMarbleRiver. You know, at the time set above
7 all members of the public will be heard. In
8 addition, written comments can be submitted to
9 the town board until June 5th, 2006, at town
10 hall, 106 West Hill Road, Ellenburg Center,
11 New York 12934.

12
13 So I think -- so I passed the test. I
14 want to just go over a couple of the basic
15 rules for how we're going to be handling the
16 public meeting or hearing here. We do have
17 speaker sign-in sheet, you know, we do have
18 some people that have signed up here, so if
19 you wish to speak at the public hearing, sign
20 in at the speaker list.

21 At the end of going through on the
22 speaker list, we will open it up for any
23 additional comments. The purpose of the
24 meeting is to hear comments from all members
25 of the public. One of the key things, keep

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, SRR, RPR

15181 494 7897

1 in mind this is not a question-and-answer
2 session. You know, nor is it a debate. The
3 intention here is to receive your comments, to
4 document them into the public record, and then
5 from there, they will be addressed to the
6 DEIS.

7 You know, comments may be addressed to
8 any aspect of the applications in the DEIS,
9 this is the appropriate forum to give the town
10 board your opinion of whether the application
11 should be approved, approved with conditions,
12 or disapproved. It is also appropriate to
13 comment on any aspect of the DEIS, including
14 asking any questions you feel were not
15 resolved in the DEIS.

16 In order to allow everyone to be heard,
17 please limit your comments to four minutes.
18 If you have -- an additional thing, if you're
19 representing a group of five or more and those
20 people are present, you will be allowed ten
21 minutes. But all the people have to be
22 present if you're representing a group.

23 If you have written comments, please
24 submit them to the board rather than reading
25 them. All written comments will be part of

1 the record. Written comments will be accepted
2 until June 25th, 2006, and you can send them
3 here addressed as wind project comments to the
4 town board, or you can also address them to --
5 the town attorney Daniel Spitzer.

6 Please when you do come up, we are going
7 to go ahead and call out the name. When you
8 do come up, please state your name clearly.
9 If you have signed up, we have your address,
10 but if as we get later, we will need to get
11 your address also, and we do have a court
12 stenographer here, so we may have to
13 periodically flag people if she doesn't catch
14 something or need something to be respoken.
15 You know, we just want to make sure that we
16 can go ahead and get everything documented
17 correctly.

18 We will go ahead and begin. Are there
19 any questions on the rules? Great. We will
20 go ahead and start with number one on the list
21 is Judy Baker.

22 MS. BAKER: I had a question but you
23 can't ask questions of a hearing?

24 MR. COPELAND: Correct.

25 MR. McNEIL: First of all, over here,

TENNYSON COURT REPORTING
Lina L. Tennyson, CSR, RMR, RPR

{518} 494-7897

1 state your name over at the mike.

2 MS. BAKER: Judy Baker. I have a
3 question on the decommissioning. I have a
4 copy of the decommissioning plan that's in the
5 Environmental Impact Statement book. I will
6 stand up as soon as I can.

7 MR. COPELAND: Okay. You will come over
8 to the microphone so we ensure that everyone
9 can hear you.

10 MS. BAKER: I can't ask a question.

11 THE FLOOR: They just won't answer it.

12 MS. BAKER: Where? The music stand?

13 MR. COPELAND: Yes.

14 MS. BAKER: The decommissioning plan,
15 I've been curious to find out what it's about
16 And in looking at the DEIS books, I have
17 Noble's here, Marble River's is similar. I
18 just wanted an explanation of the
19 decommissioning plan because I can't seem to
20 get it anywhere. You have it but I will enter
21 it into the record and I will hope someone
22 would explain it.

23 MR. COPELAND: Okay. Thank you there,
24 Judy. I do apologize on the format of the
25 meeting of that -- it cannot be a question and

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RFR

15181 494 7897

1 answer. I know one of the things I've been to
2 half of the town board meetings here and it's
3 been a very exciting and dynamic process
4 because it is a good question and answer and
5 back and forth and unfortunately, just to
6 ensure that we cover everything under the
7 SEQRA process, that gets very dangerous, so
8 unfortunately our lead counsel has given us
9 strong advice that no, we can't allow
10 basically a debate or a question or answer.

11 THE FLOOR: That's your legal counsel but
12 the law states that a public hearing is for
13 questions, you're encouraged to ask questions
14 at a hearing.

15 MR. CORRIAND: No. No. And now it's in
16 the record and we will -- you will go ahead
17 address it. I wanted to explain the reason
18 why in a lot of other town boards would
19 normally come right forward with a the
20 answer per se or describing it, yes.

21 MR. McNEILL: Let me add, it's the same
22 rules, same meeting that the IDB had here last
23 week and we are going to go by the same rules,
24 we don't have time to explain everything.
25 It's on the website. You have had a chance to

1 read it. We are using the same rules that the
2 IDA did.

3 THE FLOOR: It's a municipal law. Try it
4 sometime.

5 MR. McNEIL: You just be quiet until it's
6 your turn to speak.

7 MS. BAER: My time is up.

8 MR. McNEIL: Well, I thought you had --
9 you left the position.

10 MR. COPELAND: Number two is Kerby
11 Selkirk.

12 MR. SELKIRK: In your opening remarks you
13 asked that if we have any comments to hand
14 them to you rather than read them. I will do
15 that. They are positive, they are here on
16 behalf of Clinton County Farm Bureau and it's
17 in there.

18 MR. COPELAND: Thank you. We have Bruce
19 and -- I guess Breault.

20 MR. BREAUET: I didn't have access to the
21 horizon DEIS because I couldn't find it but I
22 did spend some time looking at the Noble DEIS
23 and I just want to say that's an amazing
24 document. And it's almost embarrassing
25 because you get so much detail, so much effort

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RPR

1518: 494-7897

1 to answer questions that just are just pretty
 2 obvious. But the one aspect of the DEIS that
 3 I thought was really interesting in view of
 4 prior meetings was the assessment of the
 5 impact on real estate values.

6 And I've been under the impression that
 7 this Wind Farm would increase real estate
 8 values because it would reduce taxes. But at
 9 other meetings we have had some very emotional
 10 testimony. We have had some people purport to
 11 be experts, one, Mr. Sherwin who said that he
 12 could just assure you that the value of your
 13 property will go down to 25 percent of its
 14 current value. That was a one meeting and
 15 another meeting he didn't -- wasn't that
 16 specific.

17 But in the DEIS they take each of the
 18 communities that are in -- near each of the
 19 community that had wind farms in New York
 20 State in the five years before and the five
 21 years after, and then there's specifically --
 22 they found all of the properties that were
 23 bought in the five years before and sold in
 24 the five years after, they paired them up with
 25 a price before and after because that's all

TENNYSON COURT REPORTING
 Lisa L. Tennyson, CSR, RMR, RPR

TSR: 494 /897

1 public record, and going through them I
 2 couldn't find a single one that didn't go up a
 3 material amount.

4 So I bring this to the attention of those
 5 people who have spoken on this topic very
 6 emotionally, and are talking about not being
 7 able to sell their property for any price. I
 8 mean, Amy, read that description and it's
 9 scientific, it's specific, and it will make
 10 you very happy. That's all I have to say

11 MR. COPELAND: Thank you. Number 4 is
 12 Dan Haas.

13 MR. HAAS: My name is Dan Haas, managing
 14 director of Noble Environmental Power. I'm
 15 responsible for the engineering, construction
 16 and operations of our facilities and I wanted
 17 to take just a minute to submit for the record
 18 tonight a study that literally was published
 19 in the last week; it's dated May of 2006.
 20 It's prepared by the Utility Wind Integration
 21 Group working together with the American
 22 Public Power Association, Edison Electric
 23 Institute and the National Rural Electric
 24 Cooperative Association.

25 This particular study, those three names

TENNYSON COURT REPORTING
 Lisa L. Tennyson, CSR, RMR, RPR

15181 494 7857

182

183

1 that I just read represent virtually every
2 utility in the United States and working
3 together with the Wind Integration Group, they
4 studied the impact and the forecasting of the
5 impact of the rapid growth of wind on the
6 utility grids on the United States.

7 I would have come to some very
8 interesting conclusions. I don't want to read
9 this whole report. Can I read a few bullets
10 points from the report that emphasize the
11 important points? Or is that not in
12 accordance with the rules?

13 MR. COPELAND: No, that would be fine.

14 MR. HAAS: As long as I stay within my
15 four minutes? The first part of the
16 conclusion, in many cases, customers' payments
17 were electricity can be decreased when wind is
18 added to the system. Further, there is
19 evidence that with new equipment designs and
20 proper plant engineering, systems stability
21 and response to a major plant or line outage
22 can actually be improved by the addition of
23 wind generation. Since wind is primarily an
24 energy, not a capacity source, no additional
25 generation needs to be added to provide backup

TENNYSON COURT REPORTING

(518) 494-7897

1 capability.

2 We have heard many statements to the
3 opposite of that. Systems stability studies
4 have shown that modern wind plants equipped
5 with power electronic controls and dynamic
6 voltage support capability can improve system
7 performance by damping power swings power
8 swings, excuse me, and supporting post-fault
9 voltage recovery. A lot of words, simply
10 means it stabilizes the system, helps to
11 improve the reliability of the system.

12 Additionally it says because of the
13 spatial variation because the turbines are
14 spread across large areas of land where the
15 wind will move across the field in varying
16 ways of wind from turbine to turbine in a wind
17 plant and to a greater degree from plant to
18 plant, a sudden loss of all wind power on a
19 system simultaneously due to a loss of wind is
20 not a credible event.

21 Primary value lies in its ability to
22 displace energy produced from the combustion
23 of fossil fuels and to serve as a hedge
24 against fuel price risk and future restriction
25 on emissions. Another point. The additional

(518) 494-7997

1 wind plant to a power system does not require
 2 the addition of any backup conventional
 3 generation since wind is used primarily as an
 4 energy resource.

5 They further detail that by saying this
 6 may introduce measurable changes to the amount
 7 of operating reserves required for regulation
 8 but what they say in two major recent studies
 9 the addition of 1500 megawatts, which is about
 10 half of what is currently planned for the
 11 state of New York, only require -- which is
 12 about ten percent penetration -- would require
 13 only increased regulation requirements by
 14 about 9 megawatts -- that's a very small
 15 amount of energy -- to maintain the same level
 16 of NERC control performance substance.

17 This is a very, very complete study,
 18 performed by and conjunction with the largest
 19 utility of association in America. I submit
 20 it for the record.] 183.1

21 MR. COPELAND: Thank you. Dan O'Neil.

22 MR. O'NEIL: Only have a couple things to
 23 say but one is, I'd like to know how many
 24 people in here are farmers? How many are
 25 older people that own land that are finding it

TERREYSON COURT REPORTING
 Lisa L. Terreyson, CSR, RMR, RFR

(518) 494-7897

1 harder and harder to a pay their taxes every
 2 year. Okay. Land values. Massachusetts,
 3 whatever in New England, are sky high,
 4 everybody's coming this way, it's lazying the
 5 land values. How many people had on fixed
 6 incomes? How many people like the farmers
 7 just lost a quarter of their income in the
 8 last two months? How are these people going
 9 to pay their taxes anymore?

10 They can't do it unless there's an
 11 alternative income. Would you rather have a
 12 nuclear plant up here? They are going to site
 13 one or two somewhere else. Would we rather
 14 have that or would we rather have this wind?
 15 I'll bet you there's half of the people here
 16 have never even gone to see the towers in
 17 Lowellville or Fenner or wherever. They hear a
 18 lot of things, most of it is hearsay. It's
 19 more tactics.

20 What it comes down to is we need income
 21 in this part of the country and what else are
 22 we ever going to have? And it's not going to
 23 enable people to keep their land they can no
 24 longer afford to. Taxes are never going to
 25 stop. They are going to keep going. And

TENNYSON COURT REPORTING
 Lisa D. Tennyson, CSR, RMR, RPK

(519) 494-7897

184

1 somewhere we have to have another income and
 2 as far as I can see, this is the only thing we
 3 are ever going to get up in this neck the
 4 woods. Thank you.

184

5 MR. COPELAND: Number 6 is Ann Britton.
 6 Ann?

7 MS. BRITTON: Yes.

8 THE FLOOR: You should have an on deck
 9 circle, like baseball.

10 MS. BRITTON: No. I'm not reading. Okay.
 11 My name is Ann Britton, I live in the town of
 12 Brandon, New York.

13 THE FLOOR: I can't hear you.

14 MS. BRITTON: My name is Anne Britton, I
 15 live in Bangor, New York. I'm a chairperson,
 16 we oppose wind farms, I'm also a member of
 17 National Wind Watch, I represent many people
 18 in the town of Ellenburg. Noble Environmental
 19 DEIS has been reviewed and should not be
 20 accepted by the lead agency, the Ellenburg
 21 town board, because it fails to demonstrate
 22 that the due concern has been given to
 23 protecting the public health and safety or to
 24 protecting the existing and environmental,
 25 natural and human of Ellenburg.

185.1

TENNYSON COURT REPORTING
 Lisa D. Tennyson, CSR, RMR, RPR

1 Specific areas of inadequacy, either in
 2 data presented or in use of the data in
 3 meaningful ways to ensure environmental and
 4 health protection are assertions of public
 5 benefits of the project. Safety including ice
 6 throw, turbine fires and seismic risks;
 7 evidence of compliance with state and federal
 8 wetlands laws; wildlife and game, animal
 9 population assessments. Compliance with U.S.
 10 Fish and Wildlife recommendations to the
 11 project sponsor, including for multi-year,
 12 multi-season, multi-weather conditions, bird
 13 and bat population assessments; compliance
 14 with New York State DEC community noise
 15 guidelines, not required since DEC is not the
 16 lead agency but lack of compliance shows
 17 indifference to reasonable noise standards as
 18 established by our state. Quality of noise
 19 assessments in modelling including the low
 20 frequency noise assessments. No mitigation
 21 of shadow flicker to affect 21 homes, no
 22 consideration of cumulative impact across the
 23 region or through time.

24 I recommend that DEIS not be accepted and
 25 present evidence to the town board to support

TENNYSON COURT REPORTING
 Lisa L. Tennyson, CSR, RMR, RPR

(518) 494-7897

185.2

1 this position. Also want to make a comment
 2 Hoyce Sherwin was incorrectly quoted. He said
 3 that the homes within a mile of the turbines
 4 would lose their value 50 percent, not 25
 5 percent.

6 THE FLOOR: 75 percent is what I said.

7 MS. BRITTON: Also, for a prime example
 8 of what happens to land in the North Country,
 9 when someone there's something on it that
 10 people don't want or it's no longer an asset,
 11 that piece of land in Altona with the
 12 transmissions lines on it, it's in the tax
 13 auction.

14 I can say that -- I have to be proud to
 15 tell everybody that Malone just passed their
 16 ordinance banning industrial turbines. They
 17 did the right thing, they did it ethically and
 18 they didn't do it in criminal ways either. So
 19 everybody that has made decisions in the town
 20 of Silesburg who have had a financial interest
 21 in this project, they have done wrong and
 22 people should be aware of that because if this
 23 was all good, guys, why are all these criminal
 24 acts being done? Why? Thank you.

25 MR. MCNEIL: You want to submit them?

TENNYSON COURT REPORTING
 Lisa L. Tennyson, CSR, RMR, RPK

] 185.3

1 MS. BRITTON: Yes. I want to submit
2 this. Sign that you're receiving this.

3 MR. McNEIL: What are they?

4 MS. BRITTON: Here is the index. Right
5 here. Thank you.

6 MR. COPELAND: Gerald Tourville.

7 MR. TOURVILLE: My name is Gerald
8 Tourville, I live in Eilenburg, I'm for the
9 wind projects. I think they are good for our
10 economy in this town, they should lower our
11 taxes. Also good for the environment. I have
12 land in this area and I don't think it's going
13 to affect the prices of our land whatsoever

14 If we don't do something for green power,
15 our future's not very bright. Everybody talks
16 about global warming. It was on T.V. again
17 tonight. If we don't do something, how can we
18 expect the rest of the country to -- to do
19 anything? You know, our area we have very
20 little to offer. We have very little to offer
21 for -- for income for the county. This is
22 something that will help. It should lower our
23 taxes. That's about all I've got to offer.

24 MR. COPELAND: Thank you. Next one on
25 the list is Norbert Kunzler.

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RRR

(516) 494-7897

1 MR. CANTLER: I'm Norbert Cantler, I'm a
2 resident of Ellenburg but my address is 94
3 Ryan Road, Chateaugay. I -- I come to support
4 the wind power. I'd like the board to
5 consider the positive aspects of this as well
6 as a negative before they make their decision.

7 We read in the papers where HydroQuebec
8 was installing wind generators. So if the
9 hydro companies are installing them, there
10 certainly must be an advantage to it. I've
11 personally seen wind power in Canada,
12 California, Belgium, Germany, and Saint Kitts.
13 I've been to the ones here in Western New
14 York. The noise is less than the noise of
15 traffic. I didn't see any dead birds under
16 them.

17 The California study says 5,000 wind
18 power generators, 4,000 dead birds in a year.
19 That's less than the birds that run into my
20 picture window and die in a year. I feel we
21 need something to help with the taxes. I
22 think this is going to give us some jobs and I
23 think it's a good thing. I hope the board
24 will consider the positive aspects as well as
25 a negative before they make their decision.

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RFR

(512) 494-7897

187

1 Thank you.

2 MR. COPELAND: Next one on the list is
3 Amy Philion.

4 MS. PHILION: My name is Amy Philion, and
5 I just want to say that I'm all for, again,
6 wind energy. The whole reason I keep standing
7 up and talking to everybody is because I feel
8 this is wrong. We shouldn't be plopped -- my
9 home shouldn't be plopped in the middle of
10 this mess.

11 Our lives we are talking about are at
12 stake. When I have children and there is
13 proven sound effects, flicker effects that
14 come off these wind turbines, it has been
15 submitted to the towns over and over and over
16 again. I have read and overlooked the DEIS
17 and there is many mistakes. There's many
18 things that the wind companies have not
19 covered fully; noise is one of them. The
20 flicker effect is another. There's also
21 issues having to do with the fires.

22 I want the board to carefully look over
23 the DIS before they make a decision on passing
24 it. I want everybody in this community, all
25 of our communities protected, not just a few

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RPR, RFR

(510) 494-9297

1 of us. Thank you.

2 MR. COPELAND: Thank you. Glen Fountain.

3 MR. FOUNTAIN: My name is Glen Fountain,
4 I live in Plattsburgh. My retirement is in 18
5 months. I have 450 acres of land in
6 Charubano and my wife and mine intentions are
7 to retire up here and with all of the
8 pollution in the air and everything, we think
9 that this is a great thing happening to the
10 community for the wind powers to come in. I'm
11 all for it and I think this is going to be
12 better for our children with a energy supply
13 and a pollution out of the air.

14 So I -- I would wish the board would
15 consider this here and let wind powers come
16 in. Thank you.

17 MR. COPELAND: Thank you. Gerard
18 Labarron.

19 MR. LABARRON: Yes. My name is Gerard
20 Labarron, I'm a lifetime resident here in
21 Ellenburg and this DIS is a environmental
22 impact statement. It's what's going to happen
23 to our community if these come in. It was a
24 lot of research been done, and not only does
25 wind companies that are in town now that's

189
TENNYSOFT COURT REPORTING
Lisa L. Tennysen, CSE, RMR, RFR

(518) 454 7827

1 been doing this research, but all over the
2 United States. This is growing. We need
3 we need green power. We got to stay away from --
4 keep our troops home because eventually we are
5 going to be fighting for oil if we don't find
6 another way.

7 And I hear so much stuff about -- go on
8 this website that website I have from the
9 Sierra Club, global warming and energy. clean
10 power comes on strong with wind energy. Then
11 I hear Union of Concern Scientists.
12 Environmental benefits are renewable energy

13 I have a lot more. There's another one.
14 Health link. Health Link Supports Wind
15 Energy Wind Energy Renanza. This is
16 something that's coming to our country and we
17 should have had it years ago. We probably
18 wouldn't be in the mess -- the country
19 wouldn't be in the mess we are today. The one
20 I really like, and everybody got this in their
21 New York State electric bill.

22 Choose the power of the next generation.
23 We can't be thinking of just ourselves, we
24 have got to think of our future. Our
25 children. They are our future. We are here.

1 yes, for a while, but we have got to figure on
 2 our future generation. Where are we going to
 3 leave them if we don't come on to something
 4 with renewable energy that they are pushing.
 5 Yes, they are pushing. For the benefit of
 6 everybody

7 All our politicians and congressmen,
 8 senators, they are all they know that we
 9 need something and what really, really helps
 10 with this, if people read these, I know a lot
 11 of times you take them out and throw them
 12 away. These people wouldn't be backing this.
 13 People would say New York State Electric and
 14 Gas, oh, they are getting theirs from coal.
 15 nuclear power, hydro. They are also
 16 sponsoring wind power.

17 So I just hope that the town board does
 18 the right thing, read the pros and cons. The
 19 pros outweigh the cons and the cons -- many of
 20 them, it's a misconception. So that's all I
 21 have to say other than I wish the board that
 22 they take a good, clear thinking of this.

23 Thank you.

24 MR. COPELAND: Thank you. Polly Cantler.

25 THE FLOOR: Patricia?

TENNYSON COURT REPORTING
 Lisa L. Tennison, CSR, RMR, RPR

1 MR. COPELAND: Patricia. I'm sorry. Yes.

2 THE FLOOR: Okay. I can't spell very
3 well.

4 MR. COPELAND: Did I pronounce anyone's
5 name right yet?

6 THE FLOOR: No.

7 MR. COPELAND: I apologize for that.

8 MS. KENZLER: I'm Patricia Cantler. I
9 have lived up here permanently for over 20
10 years. Spent 15 years before that in the
11 summers. I am thrilled that we are going to
12 hopefully have clean, renewable, non-polluting
13 energy that's going to benefit the world, not
14 just our community. And it's also going to
15 provide an opportunity hopefully for the
16 youngsters that are growing up here to have
17 jobs other than going to prisons or leaving
18 the area.

19 That we can be part of a forward-moving
20 movement that is going to be beneficial for
21 everyone. Not just us here, but everyone in
22 the world. And I hope that our board will see
23 that, and I look forward to seeing the wind
24 towers. I've traveled, I've seen them in lots
25 of places, my brother has them a few miles

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSS, RMR, RPR

(518) 494-7897

191

1 From his house, I've been going there for 7
 2 years and I finally stopped to look to see
 3 where they are. And when people talk about
 4 scars on the land, well, if you're true
 5 ecocritics, then why aren't you building your
 6 houses in the holes in the ground?

7 I see an awful lot of us with our homes
 8 above the ground, silos and barns. You can
 9 consider those scars on the land as well. And
 10 the roads that we chose to pave, those are all
 11 also scars. I think that our wind towers are
 12 truly a beneficial thing for our community.

13 MR. COPSLAND: Okay. The next one on
 14 list is Joseph Kramer.

15 MR. KRAMER: My name Joseph Kramer, I
 16 live in the town of Ellensburg on Speed Hill.
 17 We need renewable energy and the whole premise
 18 of this is to have it, have it in the fashion
 19 of windmills, and have it so that all people's
 20 involved, pro and con, are supposed to live in
 21 harmony with this.

22 The DEIS reports that I've seen leave a
 23 lot of things incomplete. Or played down.
 24 Wind noises, impacts to wildlife, things
 25 people don't even think of. Water

} 192

1 contamination that may surface come to surface
2 years from now. All this doesn't seem to be
3 of concern. It's of concern to me and a lot
4 of people.

5 Again, I'll interject that we do need
6 renewable energy but if this is just quickly
7 thought of, just to hurry up and get it in
8 without protecting everybody, except the
9 people who really don't care too much because
10 maybe they are gaining something by leading or
11 whatever, more power to them. But this is
12 not, from what I see, harmony for everybody
13 involved. Especially when we could have big
14 problems later on in the future with
15 potential -- I'll just named a few things,
16 devaluation of your property.

17 Somehow or other I can't see if all this
18 decrease that's going to be taken up by
19 windmills, so much so, that it's kind of hard
20 to build a home or start a new business. This
21 is one of the complaints keeping people here.
22 Not sending them away. Who will want to build
23 in an area where there's potential noise
24 problems, contamination, flicker problems,
25 shadow flicker.

1 I just can't see where anybody -- and
2 taxes -- if you build a new home, you've going
3 to pay top dollar for taxes. Right off the
4 bat if you're surrounded by the intensity of
5 these places, your property probably will be
6 devalued.

7 I don't see where they are going to make
8 adjustments to bring down the taxes to meet
9 the new devalue price of your property. This
10 to me is a conflict. It's a conflict of
11 people paying taxes and the tax money that's
12 being distributed to the county, the board,
13 the school, it just doesn't add up. It just
14 does not make sense.

15 There are so many things that I see that
16 I don't know, I'm awestruck. I don't know
17 where to begin. Things that nobody seems to
18 care about. Radio waves. In those reports it
19 just says there's no not enough there's
20 no coordinates supply to give anybody on radio
21 waves.

22 MR. LEVY: Do you want to try to wrap it
23 up?

24 MR. KRAMER: Okay. Anyway, that's all I
25 have to say. I just hope that the board does

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RPE

(515) 494-7897

192

1 not just make snap decisions and go with this.
2 They should follow through with the -- and
3 check out the inaccuracies of this report.
4 Because I see many loop holes in it that are
5 not right. Thank you.

6 MR. COPELAND: Thank you. I guess first
7 of all, is there anybody that signed up on the
8 list that I did not call? Is there anyone
9 else that would like to speak?

10 THE FLOOR: Can I speak?

11 MR. COPELAND: Yes.

12 MR. SILVESTER: Peter Silvester, I live
13 on 25 Vanderboeght Road in Ellenburg Center.
14 I see there's a lot people in here that see
15 all the big advantage to the wind farms. I
16 think most of it is money that they are
17 looking at to support this area. Taxes seem
18 to be a big issue. I talked to the board here
19 and I'm very concerned about this --- all this
20 tax money that may be coming into this town
21 from these wind towers is that going to cause
22 troubles with us losing some of our state
23 funding, federal funding because they see this
24 big monetary value that we have in these wind
25 towers?

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RPR

18181 494 7897

193

1 So is the tax increase that you're going
 2 to receive from these end up being nothing but
 3 a wash to start with and our taxes end up
 4 staying the same. Now corporate America
 5 they have a very good job in devaluing their
 6 assets or devalue or not showing the property
 7 in which they do make from them.

193.1

8 I mean, is it five years down the road,
 9 are the lease holders on these wind towers
 10 going to get the money in which they said they
 11 were going to get? You know, this is all
 12 these questions that need to be arised, you
 13 take this is the windmills is going to
 14 have -- cause a place for our kids to stay.
 15 There's not a lot of jobs with these wind
 16 mills. Maybe you'll get a tax break, maybe
 17 you won't.

193.2

193.3

193.4

18 I don't there has to be something
 19 else in this community. These wind towers
 20 isn't going to boost this economy in this area
 21 that much. Now, I don't keeping there's
 22 not enough jobs there. Now, another thing is,
 23 there's talks that these things will be coming
 24 down in 15 years.

193.5

25 Now I want the town to realize, corporate

1 America shouldn't be putting a burden on the
 2 towns to make sure these things are
 3 decommissioned. These decommission, the money
 4 should be set right there today, when they go
 5 up, so that these things come down, I hear
 6 that the decommission drawn from 300,000 to
 7 45,000. I don't understand that all that.

8 Maybe there's some clarifications they
 9 could make on this. The environmental study,
 10 I hear -- I haven't even heard that -- has
 11 there been a whole seasons in which this
 12 environmental study is done. Spring to fall,
 13 the migrating birds, you know the birds coming
 14 back in the spring. Has the deer been
 15 assessed? The turkey? All that doesn't seem
 16 to be in there. There are -- all these are
 17 just things that need to be looked at.

18 Now, I know the money is a major thing to
 19 you people but you can't be blind to all that
 20 too because down the road, corporate America
 21 could give a hoot less what happens to
 22 Ellenburg Center. Thank you.

23 MS. CORRIANE: Thank you. Is there
 24 anyone else?

25 MR. LYONS: My name is Mark Lyons, I'm a

TENNYSON COURT REPORTING
 Lisa L. Tennyson, CSR, RMR, RFR

TELE: 494-7597

193.5

193.6

1 director of project development for Noble
 2 Environmental Power. I wanted to respectfully
 3 submit for the record in this hearing
 4 signatures of 158 people who support this
 5 application for Noble Environmental. Noble
 6 Eileenburg.

194.1

7 I also wanted to take a moment to address
 8 some of the questions that were asked first of
 9 all Judy Baker asked early on about the
 10 decommissioning plan just quickly. The -- the
 11 decommissioning plan is a is a required
 12 aspect of our application for a town permit in
 13 Eileenburg to explain to the town how turbines
 14 would be removed at the end of their useful
 15 life and goes into great detail about the
 16 steps that will be taken and the mitigations
 17 that will be taken to make sure that the area
 18 is restored after a wind turbine is removed.

194.1

19 Another aspect of the decommissioning
 20 plan is that we have posted security in the
 21 unlikely possibility that we or somebody else
 22 wasn't around to pay for the decommissioning,
 23 the town will be, already has the money in the
 24 bank to do the decommissioning themselves.
 25 This is all spelled out in great detail in the

194.2

TENNYSON COURT REPORTING
 Lisa L. Tennyson, CSR, RMR, RPR

(518) 494-7897

1 DEIS, and the amount of money that is posted
 2 from time to time is updated on an annual
 3 basis for any economic assumptions that may
 4 change from year to year.

5 Question was asked about the impact on
 6 state aid from the taxes that the project
 7 would pay; that's a very good question. Under
 8 our proposal, Noble Ellenburg, our proposal is
 9 to pay payments in lieu of taxes rather than
 10 traditional taxation. One of the nice aspects
 11 of payments in lieu of taxes is they do not
 12 have any impact on state aid, so there is no
 13 give back on the state aid for the schools
 14 that are under pilot payments, where as there
 15 would be under traditional taxation.

16 The economic benefits that are projected
 17 from the projects are a matter of public
 18 record but in answer to people -- a gentleman
 19 who was concerned about the economic benefits,
 20 I think it's on the order of \$100 million that
 21 would be brought to the local economy from
 22 this project over 20 years from job salaries,
 23 spending, and economic multipliers using
 24 actual empirical economic multipliers from
 25 Clinton County.

TENNYSON COURT REPORTING
 Linda L. Tennyson, CSR, RMR, RFR

(518) 494-7897

10A 3

10A 4

1 I'd like to offer for the record a couple
2 of reports that addressed the issue of impact
3 of windfarms on property values, that's a
4 question a number of people have asked. First
5 of all, there's a recent project report
6 submitted by a gentleman, partial fulfillment
7 for master of science, environmental policy at
8 Bard College entitled impacts of windmill
9 visibility on property values in Madison
10 County, New York, and his conclusion is that
11 there is no impact. And so he goes into great
12 detail on that conclusion.

13 Another report, the effect of wind
14 development on local property values done by
15 the renewable energy policy project in 2003,
16 study ten, wind parks around the country at
17 the time. Their conclusions were that we
18 found that for the great majority of projects
19 the project property values actually rose for --
20 quickly in the view shed than they did in the
21 comparable community. Moreover, values
22 increased faster in the view shed after the
23 projects came online than they did before.

24 And finally, after projects came online
25 values increased faster in the view shed than

TENNYSON COURT REPORTING
Lisa L. Tennyson, CSR, RMR, RPR

(518) 494-7897

19A.5

1 they did in the comparable community. And
 2 finally, a report called economic impacts of
 3 wind powers and Kidakis (phonetic) County,
 4 Oregon, study 22, wind projects, their
 5 effects on property values, conclusion was use
 6 of wind turbines will not negatively impact
 7 property values.

1995

8 So all these are well documented, all the
 9 information is here, they're peer reviewed and
 10 they uniformly support the conclusion that
 11 wind farms in looking at wind turbines do not
 12 impact residential property values. Thank
 13 you.

14 MR. COPELAND: Thank you, Sir?

15 THE FLOOR: He answered it.

16 MR. COPELAND: Is there anybody else?
 17 Okay. Well, we -- from here, I -- you know,
 18 thank everyone for submitting the comments.
 19 What will be occurring now is we will be
 20 taking the comments, reviewing them one by
 21 one, and then addressing them in the final
 22 when we come out with the statement for the
 23 final environmental impact statement. From
 24 here I can turn it back over to you.

25 MR. McNEIL: Okay. Well, all I need is

**Town of Altona, Clinton County
NOTICE OF JOINT PUBLIC HEARING
ON DRAFT ENVIRONMENT IMPACT STATEMENTS
AND WIND ENERGY OVERLAY DISTRICT REZONING/
SPECIAL USE PERMIT APPLICATIONS
Noble Altona Windpark, LLC Application
Marble River, LLC Windfarm Application**

Notice is hereby given that the Town Board of the Town of Altona will hold a public hearing at 7 p.m. on May 26, 2006, at the Altona Town Hall, 3124 Miner Farm Road, Altona, New York, to receive comments on the (1) application for wind energy overlay district and special use permits and (2) Draft Environmental Impact Statements (DEISs) submitted by Noble Altona Windpark, LLC for the construction and operation of Wind Energy Generating Facilities and related infrastructure (electric lines, access roads, substation) in the Town. The Town Board of the Town of Altona, acting as Lead Agency under the State Environmental Quality Review Act, had determined that the Noble Altona Windpark, LLC project could have a significant adverse impact on the environment, and therefore issued a positive declaration and ordered the applicant to prepare a DEIS for the project. At the hearing the Board will also receive comments on all cumulative impacts of the project. The Application and DEIS are available for review at the Town Hall, 3124 Miner Farm Road, Altona, New York, or on the internet at <http://www.noblepower.com/our-projects/altona/AltonaDEIS.html>.

At the time set above all members of the public will be heard. In addition, written comments can be submitted to the Town Board until June 6, 2006 at Town Hall, 3124 Miner Farm Road, Altona, New York 12910

Altona, NY 12910

Re: Noble Altona Windpark

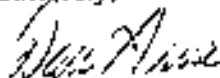

Dear Mr. Ross,

At the public hearing held on Friday, May 26th regarding the Draft Environmental Impact Statement for Noble's Altona Windpark, one Altona resident produced a distorted photo of wind turbines from the Maple Ridge project. The photo originally ran in the Watertown Times in November of 2005, and has been widely circulated by opponents of windparks.

Shortly after the photo was published, I accompanied a group of Clinton County residents on a bus trip to visit the Fenner and Maple Ridge windparks. We were able to locate the same house that was in the original photo, and a Noble staff member who was also on the trip took the attached picture to show how distorted the original photo was.

I am submitting this photo to correct the record. If you have any questions, please do not hesitate to contact me.

Sincerely,

Dan Grue

Comments on the Proposed Noble Altona Windpark

Comments on the Noble Altona DEIS

Comments by Citizens Campaign for the Environment

C. E. Churubisco, New York

May 26, 2006

Thank you for the opportunity to comment. My name is Dereth Glance, Program Director with Citizens Campaign for the Environment (CCE). Supported by over 80,000 members, CCE is a non-partisan, non-profit advocacy organization working to protect the natural environment and public health. Our work is based on a philosophy of pollution prevention, conservation, and environmental sustainability.

CCE strongly supports increased investment and development of clean, renewable energy and in particular wind energy that has undergone a rigorous environmental review. CCE strongly believes that residents and local governments should make informed decisions on wind power projects based on their individual and specific merits and concerns, with the opportunity review proposals in an open and meaningful process.

As most of us already know, the consumption of energy generated by fossil fuels and nuclear power has serious impacts on human health, wildlife, plants, and the natural environment. The long list of detrimental consequences from our reliance on fossil fuel combustion and nuclear fission include, but are not limited to: acid rain, urban smog, higher rates of lung disease and heart failure, oil spills, contaminated drinking water, rising sea levels, mining impacts, global warming, ecosystem damage, nuclear waste disposal, national and global depletion of finite energy sources, and conflicts over the world's dwindling non-renewable sources. *In particular, increasing concentrations of mercury in fish and wildlife, as well as, the devastating effects of acid rain will continue to significantly impact the environment, economy, and character of the North Country.*

In general CCE strongly supports wind power projects that have undergone rigorous environmental review, for the following reasons:

- *Wind power is emission free.* In contrast to coal, oil, and gas plants, wind facilities do not burn fossil fuels and thus do not produce air pollution. Wind power does not require millions of gallons of water each day for cooling purposes, like fossil fuel and nuclear plants. Wind power is a commercially available, proven clean technology.
- *Wind power is independent of imported fuels.* Once constructed, a wind facility requires no fuel. This reduces our dependence on imported oil and gas, much of which comes from unstable areas of the world. In times of rising and volatile fuel

CCE believes that the Altona Windpark positively benefits the environment, local rural economy, and public health. Over the 20 years, the Altona Windpark is expected to reduce precursors to acid rain, Nitrogen Oxide (NOx) and Sulfur Dioxide, 4,593 and 9,603 tons, respectively. Additionally over 2.8 million tons of Carbon Dioxide (CO2), the chief green house gas contributing to global climate change (global warming) will be displaced as a result of this clean energy project.

In closing, CCE appreciates the opportunity to discuss our perspective with the residents of Altona. Wind power offers innumerable environmental and economic benefits to the local community, the region, our state, and the nation as a whole. Deciding to host a wind farm in your community is a big decision. It is one that must be made considering all the facts and inclusive of all points of view. There are issues, such as aesthetics, that we must agree to disagree on. Many find these sleek turbines to be examples of "kinetic art," that hold the promise of a better future for our children. And just like other examples of art, there are those that disagree. These perspectives, while both valid, should not be the sole determining factor of whether your community decides to host a wind farm.

Thank you for the opportunity to comment.

Sincerely,

Dereth Glance

Citizens Campaign for the Environment

June 2, 2006

Larry Ross
Town Supervisor
Town of Altona
PO Box 79
Altona, New York 12910

Dear Mr. Ross,

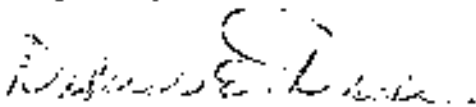

I am writing this letter in opposition to the proposed Noble Altona Windpark. I am at this time:

1. Requesting under F.O.I.L. the dates of all meetings that were published in the *Press Republican* regarding the project.
2. Requesting under F.O.I.L. the date that the Town of Altona representatives first met with representatives from Noble Environmental Power to discuss this project or took any action regarding this project.
3. Submitting evidence that the proposed project would not be in the best interest of the majority of your constituency.

As you are aware, I am extremely disappointed in the manner in which the taxpayers of Altona were brought into this process. Still today, I find that most of the people with whom I speak are either uninformed or grossly misinformed regarding this project. I was especially concerned when I received the latest newsletter from the Town of Altona and on the back of your letter was a full page advertisement that stated "...please come out and tell NACS and the IDA that YOU support windpower!" It seems that it is the Board's responsibility to inform the community and to remain impartial. Furthermore, if any Board Member or their family members will be personally benefitting from the project, they should excuse themselves from the process to avoid any legal Conflict of Interest.

I would like to further state that my opposition to this project came only after relentless hours of research on both the pros and cons of Corporate Wind Power. I have summarized my concerns in an effort to be concise in the hopes that all Board Members will take the time to consider each of these points.

Respectfully submitted,

Deborah E. Drake

cc: Board Members
Conestoga-Rovers & Associates

Conestoga-Rovers & Associates (CRA) were retained by the Town of Altona to oversee the environmental assessment process for the development of the Noble Altona Windpark. Their role is to act on behalf of Altona to review the environmental impact and advising the Town on these impacts so that the Town can act on their own best interests. **THE ALTONA TOWN BOARD HAS AN OBLIGATION TO MAKE SURE THAT ALL ALTONA RESIDENTS AND TAXPAYERS ARE MADE AWARE OF THESE CONCERNS. IF IT IS DEEMED THAT THE PROJECT GO FORWARD, EACH OF THESE ISSUES MUST ADDRESSED IN A SPECIFIC AND CONCRETE MANNER. I RECOMMEND THAT THE BOARD DEVELOP A COALITION TO STUDY THESE ISSUES AND TO INFORM THE PEOPLE OF THE TOWN OF ALTONA OF CONCERNS.** (It is my opinion that the people of Altona have not been sufficiently informed by the Altona Town Board.)

CRA indicates that the installation of 68 1.5 MW wind turbines in Altona will have “a significant impact on the look and ultimate land-use of the overall area.” (Are the people of Altona aware of the tremendous impact at the cost of all of us and with the benefit of only a few?)

CRA indicates that Noble “did not measure ambient noise background data for the purpose of assessing compliance with the local law, nor for the assessment of cumulative noise impacts...” (Why not?)

CRA noted that two participants predicted to be at the noise limit “had no buffer for error”. (In my opinion, this is unacceptable.)

CRA noted that should predicted (keeping in mind that Noble did not measure ambient noise background) noise levels be “slightly higher, or if homeowners are sensitive to noise levels, nuisance complaints and/or adverse noise impact may be experienced.” (Has the board informed people of this? Noise caused by turbines have been linked to anxiety and depression).

CRA recommended Noble “use the methodology for their proposed project to assess cumulative noise impacts, and identify all residences that will experience a sound pressure level increase of at 6 or more dBA beyond background levels. ...”. Noble concluded from their analysis that **sound pressure increases of more than 6 dBA over existing conditions would occur at most on and off-site residences in the vicinity**”. (Noble admits to sound pressure increases...what are we doing about it?)

CRA indicated that “wind turbines may be visible from most locations within the Town, possibly up to distances of 10 miles.” Noble concluded that the project will also “be visible from points along the northern edge of the Park, including Lyon Mountain. In addition, it was also note by Noble that FAA lighting will be visible from many areas within the Project Area”. (Are people in this town and in Lyon Mountain aware of this?...Aren't we concerned with light pollution?)

The report noted that approximately “42 homes in the Project Area would potentially experience shadows on the house as a result of the wind turbines.” “Each tower will occupy a 40x40-ft. lot.

The construction footprint for each turbine will be 200 ft. x 200 ft.” (How will this sunlight deprivation affect depression, gardens, pools, heating cost, etc. Has the Board made any effort to contact the people who live in these 42 homes?)

CRA recognizes **“that wetlands are numerous within the project area and range in size from less than 1 acre to greater than 130 acres.”** **“There are also 34 perennial and intermittent water bodies in the project area”.** Some of these **sustain salmonid reproduction.** (How will this affect the wildlife in the area? Water does not stand still...how will fish and other species dependent on the wetland ecosystem be affected in and out of the project area?)

CRA reports that 17.6 miles of access roads will be created and that access roads will be constructed in a 40 ft. wide cleared area. Roads will be maintained at 35-ft. widths during construction and then reduced to 16-ft widths as permanent access roads. **“Noble has stated that permanent and temporary impacts to wetlands related to construction of access road, collection lines, transmission lines and turbine sites..”** **“...permanent and temporary impacts to agricultural lands..”** **“...permanent and temporary soil impacts..”**(This constitutes a tremendous amount of disruption that does not seem to offset the inefficient, costly and minuscule amount of power that will be generated from this project).

CRA's report notes that there will be **disturbance of habitat, a need to regenerate habitat, habitat fragmentation, disturbance and displacement impacts.** (What will happen to the recreational fishing and hunting that is a vital part of our culture and economy?)

CRA's report notes that lighting of turbines and other infrastructure have the **potential for attracting night migrating songbirds and similar species.**

CRA's report notes that **“..the Breeding Bird Study was conducted for only 3 days in the Spring and 3 days in the fall. Additional study seems warranted.”** (Are we demanding that additional studies be conducted, and if so, are a few days of studies sufficient to understand the impact of breeding on all species?)

CRA recommended the following avian study **“a post-construction study of collision fatalities should be conducted to provide information on the number and type of fatalities that occur...”.** (Are we going to insist on this and if large number of birds are being killed, what will we do?)

In regards to Noble's response that sufficient avian studies were completed, **CRA disagreed with Noble's conclusions.** (If the CRA does not agree with Noble's conclusions, what are we going to ask of Noble?)

Numerous other concerns were raised by CRA including existing seismic hazard, delivery vehicle weight (up to 212,00 pounds), proximity to YMCA Camp, accuracy of cost of decommissioning turbines including access road removal and disposal costs and set-back distances from blasting operations. (All of these issues raise numerous concerns and questions for me as I am sure they will for many taxpayers of the Town of Altona).

WHAT THE NORTH COUNTRY NEEDS TO KNOW ABOUT WINDPOWER

Excerpts taken from "Big Money" discovers the huge tax breaks and subsidies for wind energy while taxpayers and electric customers pick up the tab.

**by Glenn Schleede*

- ★ **Enormously generous tax breaks and subsidies are available in the US for producing electricity with wind turbines.**
- ★ **"Wind Farms" are not environmentally benign. Instead, wind energy has high economic, environmental, ecological, scenic and property value costs.**
- ★ **Wind turbines produce only small amounts of electricity and that electricity is unreliable and low in value.**
- ★ **Often times local officials don't realize that they have been misled about the true benefits and cost of wind energy.**
- ★ **In the US, "wind farms" are being built primarily for tax avoidance purposes, not because of their environmental, energy or economic benefits.**
- ★ **Large amounts of capital are being spent on projects that produce only small amounts of unreliable, low value electricity.**
- ★ **Wind Power companies have consistently overstated the environmental benefits and understated the environmental, ecological and economic cost of wind energy.**
- ★ **"Big Money" organizations are moving aggressively to build "wind farms" and seek more subsidies. J.P. Morgan has surfaced as the organization financing Noble Environmental Power.**
- ★ **The public, media and government have been grossly misled about the costs and benefits of wind energy. As a result some 300 citizen-led opposition groups have emerged.**
- ★ **Huge windmills, often taller than the US Capitol, produce very little electricity. In 2003, windmills produced 41/100 of 1% of the electricity produced in the US.**
- ★ **Windmills may begin producing some electricity at 8 MPH, reach rated capacity around 33 MPH and cut out around 56 MPH resulting in intermittent, volatile and largely unpredictable**

- electricity.
- ★ The costs of tax breaks and subsidies shift the tax burden and costs from “wind farm” owners to ordinary taxpayers and electric customers.
 - ★ Wind turbines need backup from other sources of electricity to balance the intermittent and volatile output from wind turbines.
 - ★ Backup sources continue to give off emissions.
 - ★ Adverse impacts of wind turbines include noise, bird kills, interference with bird migration paths and animal habitats, destruction of scenic vistas and distracting blade “flicker” and aircraft warning lights, and lowering property values located near the turbines.
 - ★ Artificially created, high priced markets for wind-generated electricity are the result of the state requiring electricity suppliers to obtain some share of their electricity from “renewable” sources. Customers can elect to pay premium prices but do not attract enough “volunteers” and ultimately the cost not recovered from customers is then spread across all of the utility’s customers and hidden in monthly electric bills.
 - ★ The big “winners” are “wind farm” owners and a few landowners who lease their land. Electric customers and taxpayers are the big “losers”.
 - ★ Tax subsidies for wind power come in the form of Federal Accelerated Depreciation, Federal Production Tax Credit, Reduction in wind farm owners’ state corporate income tax liability, property, sales and other state and local tax reduction or elimination, Public benefit funds, Renewable Portfolio Standards, Mandated “green energy” purchases, “Voluntary” programs offering “green” electricity at a premium price.

**Glenn Schleede*

-currently semi-retired after working on energy and related matters in government and the private sector for over 30 years.

-from 1992-2000 maintained a consulting practice (EMPA), providing analysis of energy markets and policies.

-prior to forming EMPA was Vice President of New England Electric System and President of its fuels subsidiary, New England Energy

Incorporated.

-In 1981 was the Executive Associate Director of the US office of Management and Budget, Senior VP of the National Coal Association in Washington (where he was employed from 1977-1981)

-Associate Director of Energy and Science of the White House Domestic Council (where he served from 1973-1977)

-Schleede career service positions in the US OMB and US Atomic Energy Commission.

-Schleede has a BA degree from Gustavus Adolphus College and an MA from the University of Minnesota. He is also a graduate of Harvard Business School's Advanced Management Program.

Schleede has been a frequent target of attacks by officials from the wind industry and have falsely accused Schleede of working for fossil-fuel industries. Schleede notes that all his work on wind energy is self-financed and he has offered leaders of the attacking organizations the opportunity to review his personal and business financial records provided that the work is done by an independent third party who can assure appropriate confidentiality of information and the work is paid for by the individual and organization making the charges and is not reimbursed or otherwise paid for by using yet more tax dollars.

To: The Altona Town Board
Re: Wind Turbine Industry

My name is Andrea Norcross. I reside in Jericho, NY. I do not agree with the implementation of wind turbines in our town.

Primarily, our household was not informed in writing of any industry of the kind being placed in the Town of Altona. This is unfortunate. Therefore, I have had to retrieve information from outside sources. This includes research, newspaper articles, and testimonies of individuals currently living near the turbines.

Specifically, the negative impact that these wind turbines produce is my main concern. I am concerned about raising a family here and guaranteeing that they will not be affected by the possibility of counterproductive effects that wind turbines generate. I am concerned about the personal well-being and quality of life of the residents in our town. I am also concerned about property value, the decrease of the animal population, and the negative visual impact that comes with these structures being put into place.

I hope that I can continue to reside in Jericho, NY.

Thank you for taking the time to read my thoughts about this important matter.

To: Town of Altona

From: Cynthia Root Baker
192 General Leroy Manor Rd

As a painter who has drawn unending inspiration from the beautiful woods of the North Country for the last 28 years, what is happening now breaks my heart.

The things that are so precious here, our safe surroundings, our beautiful landscape, and the extreme character of this area is going to be destroyed and turned into an industrial wind park? The stillness that has nurtured me, the beauty that has awed me, and the natural wildness that has inspired me will be gone forever. Why? Because someone offered the right price?

Wake up people! We shouldn't sell out so cheaply! These giant invasive wind turbines aren't even efficient, and will satisfy very little of our energy needs. Our safety, our health, our peace and our way of life should not be for sale!

I'm visually sensitive, noise sensitive, vibrationally sensitive, electromagnetically sensitive, ethically sensitive and morally sensitive. I will be gone too.

Sincerely,

A handwritten signature in black ink that reads "Cynthia Root Baker". The signature is written in a cursive, flowing style with a long horizontal flourish at the end.

Review of the Noble Environmental DEIS for Altona, NY

Nina Pierpont, MD, PhD
19 Clay St.
Malone, NY 12953
(518) 483-6481

May 31, 2006

Abstract:

- 1) **Benefits claimed for wind power are inflated by failure to use realistic, published efficiency figures. No evidence is presented to support industry claims that production of wind-generated electricity lessens fossil fuel consumption.**
- 2) **The quality of the DEIS is superficial and presentation is deceptive. The avowed goal of the company which prepared the DEIS is fast permitting, not protection of environment or community.**
- 3) **Safety with regard to turbine fires, lightning strikes, and ice or blade throw is not adequately addressed.**
- 4) **Data on turbine stability in the presence of earthquakes is not presented. The DEIS preparers failed to note an earthquake of magnitude 5.1 which occurred 33 miles from the proposed project area in 2002 and caused \$4 million worth of damage, and another earthquake of magnitude 3.7 five miles from the proposed Project area this year. Setback of 500 ft. from roads and 587 ft. from on-site buildings, as specified in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances, is not adequate to protect the public should one of these slender 400 ft. structures with 100 tons of equipment near the top fall over.**
- 5) **Noise standards adopted in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances do not comply with community noise standards put forward by non-industry agencies such as the NYS DEC or the World Health Organization, and as such will not protect the public from the health impacts of excessive community noise. Noise modeling did not use up-to-date models of the known distant propagation of annoying noise from wind turbines under conditions of nighttime atmospheric stability. Noble Environmental's acoustics consultant is well aware of these models and was negligent in not requiring their use. While recognizing that wind turbines produce low-frequency noise, the acoustics consultant appears to be ignorant of the medical research literature on the brain, lung, and heart pathology caused by long-term exposure to noise at frequencies too low to be heard.**
- 6) **Shadow flicker produces symptoms of motion sickness in susceptible people and has the potential to trigger seizures in individuals with epilepsy.**

- 7) Bird and bat studies are inadequate with regard to standards communicated by USFWS to Noble with regard to migratory birds, threatened and endangered species, and eagles. No population figures can be derived from the data obtained and presented in the DEIS. Multi-year studies were not performed. There is no adequate baseline created here by which to use this wind turbine installation to study the effects of wind turbines on bird and bat populations.
- 8) The non-avian wildlife section shows incompetence. As in (7), no population data is presented on which to base studies of the effects of wind power development on game species such as deer and bear.
- 9) It is not clear in the DEIS that appropriate state and federal (Army Corps of Engineers) oversight and permitting has taken place with regard to wetlands within the project areas. In fact it has not, according to the responsible Army Corps of Engineers official I spoke to on May 31, 2006, at which time review of the Clinton Project application was in the early stages and review of the Ellenburg and Altona Project applications not yet under way. Permits are required for all activities impinging on any wetland or stream connected ultimately to a navigable waterway. Federal review under the Fish and Wildlife Coordination Act and the National Historic Preservation Act are also required, triggered by projects falling under Army Corps of Engineers jurisdiction.

Introduction:

I am a graduate of Yale (BA 1977, Biology), Princeton (PhD 1985, Population Biology), and Johns Hopkins (MD, 1991). Population Biology is ecology, evolution, and animal behavior. I studied the behavior and ecology of Amazonian birds, spending two years in the field in South America forests. Besides this, I did a year-long (1985-6) post-doctoral fellowship in ornithology at the American Museum of Natural History, NYC. I have lived in this region (Franklin County) of NY State, where I practice behavioral and developmental pediatrics, for nine years. I am familiar with local ecology as well, as a physician, with health and safety issues.

It is "the intention of the Legislature that the protection and enhancement of the environment, human and community resources should be given appropriate weight with social and economic considerations in determining public policy, and that these factors be considered together in reaching decisions on proposed activities" (SEQRA 617.1 Authority, intent, and purpose.). The first issue to be considered here is thus whether there is sufficient social and economic gain anticipated from this project to make it worth the environmental impacts it will have.

SEQRA emphasizes the importance of cumulative impacts from simultaneous or subsequent projects in addition to the specific current project. Industrial wind generating installations are in the planning stages across northern New York State from Cape Vincent to Plattsburgh. The first wave of a large installation has already been built on the high ground east of Lake Ontario (Tug Hill Plateau, Lewis County). The current Noble Environmental applications represent only "Phase 1" in the locations of Ellenburg, Clinton, and Altona. Between Noble Environmental and Marble River, the two companies operating in Franklin and Clinton Counties, 860 turbines are currently proposed (data from applications to the New York Independent Systems Operator [NYISO]).¹ The cumulative viewpoint significantly alters how we view issues of land use, agricultural land preservation, community character, and impacts on wildlife. In the

¹ www.nyiso.org. See "NYISO Interconnection Queue," under NYISO Planning, under the Services drop-down menu.

Noble Environmental DEISs, the cumulative viewpoint is limited to their own current projects and does not consider the wider problem of many hundreds of wind turbines spanning the length of the highlands above the St. Lawrence River Valley from Lake Ontario eastward. Moving further west, turbine installations are also in planning south of Lake Ontario and throughout rural upstate NY.

I will address first the issue of social and economic benefits, and then the following areas in which I have expertise and find Noble Environmental's assessment of environmental risks to be inadequate or faulty: creation of hazards to human health, noise levels, wildlife effects (including game animals and migratory birds), and wetlands.

1. Assertions about the project's public benefit

Noble Environmental makes assertions about the positive effects its product, wind-generated electricity, will have on reduction of emissions from other power plants (DEIS p. 4 and 1-16). These assertions are based on the stated assumption (p. 1-16) that this 102 MW windplant (68 turbines x 1.5 MW per turbine) will indeed deliver 102 MW of electric power to the power grid. This assumption is inflated and deliberately deceptive with regard to the project's public benefits. General Electric, the turbine manufacturer, in a report to the New York State Energy Research and Development Authority (NYSERDA) on March 4, 2005, stated, "Capacity factors of inland wind sites in New York are on the order of 30% of their rated capacity. Their effective capacities, however, are about 10% [of rated capacity], due to both the seasonal and daily patterns of the wind generation being largely 'out of phase' with the NYISO load patterns."² The erratic nature of wind and the impossibility of matching supply to demand with wind-generated power make it the least preferred power source for the Independent Systems Operator (New York State power grid), which does not want the proportion of wind-generated power to approach current goals of the NYS Renewable Portfolio Standard (25% for all renewable sources) because of grid stability issues and because the NYISO's need is for capacity (power generated at the specific time to match needs) not energy (power generated at other times) (testimony presented at the RPS Hearing of the Energy Committee of the NYS Assembly, March 7, 2006). NYSEDA further states that wind power can produce, at most, 1.7% of NY State's electricity needs.³ Noble Environmental is aware of these limitations and writes with intent to deceive about proposed project benefits in the DEIS.

It would be possible to present actual data from existing wind turbine installations in New York State (Fenner, Weathersfield, and Tug Hill) on electricity generation and consumption and matching data on state power generation from other sources over the same and earlier time periods to see if, in fact, fossil fuel consumption is reduced by the presence of wind generation, and if so, by how much. Since wind generation is erratic, it would be useful to know which alternative sources (fossil fuel vs. nuclear vs. hydro) are dialed down when wind plants are producing. The strength of this analysis could be enhanced by similar information from the states of Vermont, Pennsylvania, and West Virginia, where there are also wind generation facilities in operation. Independent analysts have difficulty gaining access to these figures, perhaps because the data are not favorable to the wind industry.

² "The Effects of Integrating Wind Power on Transmission System Planning, Reliability, and Operations. Report on Phase 2: System Performance Evaluation," prepared for NYSEDA by GE Energy et al., March 4, 2005, p. 7.16. See also "The Effects of Integrating Wind Power on Transmission System Planning, Reliability, and Operations, Report on Phase 1: Preliminary Overall Reliability Assessment," prepared for NYSEDA by GE Energy et al., February 2, 2004. Both are posted on the NYSEDA website: www.nyseda.com

³ Ibid.

2. General quality of the DEIS

The Noble Environmental DEIS is a document remarkably naive of useful data. Data there is, or at least lists of information and tables of numbers which were measured in some way, but the measurements and numbers stop short of demonstrating anything meaningful, even when comparisons are made. Ecology and Environment, Inc. has created for Noble Environmental a soothing, pleasing, and mind-numbing document whose conclusions, section after section, are unsupported assertions of a most vague nature. Problems are masked by inadequate data gathering or presentation. There is no interest in realistic solutions even when problems are documented. The document relies heavily on the unspoken assumption that our presumption is that the project has no environmental impact. If this is the case, inadequate data leads us back to the conclusion that the project has no environmental impact, because the presumption, or null hypothesis as it is called in science, has not been disproven. In reality our presumption in requiring a study of environmental impact is that the impact is significant, and the burden of proof rests with Noble Environmental and its contractor, Ecology and Environment, to demonstrate that the project's environmental impact is sufficiently low relative to the social and economic benefits to be gained. If the data is inadequate or not pertinent to the problem at hand, then our presumption of significant environmental impact has not been disproven.

It is hardly surprising that the creators of this document lack commitment to a scientific approach or to environmental protection, however, given the website description of what Ecology and Environment offers its clients:

"The right environmental permitting strategy can mean the difference between spinning assets and a multi-million dollar write-off. E & E provides strategic environmental permitting approaches to get you the permits you need ahead of schedule and with the operational flexibility you need. From site selection and planning through construction, startup and long-term compliance, E & E's nationwide team specializes in environmental consulting services. We get the approvals you need to get your project on-line ahead of the competition." (<http://www.ene.com/services/power.asp>)

This approach is not the intent of SEQRA.

The graphic of a wind turbine presented in several locations in the DEIS (Figure 1-3, for example) is deceptive because it does not represent rotor size accurately relative to the height of the tower. Hub height is marked as 80 m, while rotor diameter, marked as 77 m, is represented graphically by a diameter only 59% of what it should be to be proportional to the hub height. Thus the rotor, whose blade reaches essentially half-way down the tower (77 m being approximately equal to 80 m), is represented graphically as a little pinwheel in this diagram. Little jagged lines are added on either side of the tower base to further the illusion that the tower is even taller compared to the rotor size. This diagram is reproduced in the Avian Risk Assessment to misrepresent the rotor-swept area, a critical concept with regard to avian impacts.

3. Safety from lightning, fires, falling turbines, dislocated pieces of turbine, or ice throw.

In section 2.29.1 and 2.29.3, the DEIS fails to acknowledge that none of the fire departments it names has the capability to fight fires in turbine nacelles (generator and gear box) 265 ft above the ground. Turbine nacelles contain significant amounts of lubricants and hydraulic fluids. Fires may be started by lightning or brake malfunction. A fire may leave wind turbine controls malfunctioning until the equipment in the nacelle is repaired or replaced, making it more susceptible to accidents.

The Altona Wind Energy Facilities Ordinance allows wind turbines to be erected 500 ft. from roads, 587 ft. (1½ times the total height) from buildings or above-ground utilities, and 1200 ft. from off-site homes. None of these distances are safe with regard to projectiles thrown from spinning 126 ft. turbine blades 390 ft. in the air, such as ice or pieces of blade, which can travel over 1600 ft. In Germany in 2003, in high storm winds, brakes on a wind turbine failed and the blades spun out of control. A blade struck the tower and the entire nacelle flew off the tower. The blades and other parts landed as far as 1650 ft (0.31 mile) from the base of the tower⁴. This was an "upwind," three-bladed, industrial-sized turbines like those in the Project; "downwind" turbines have not been built since the 1980's. This distance is nearly identical to calculations of ice throw from turbines with 100 ft. blades rotating 20 times per minute (1680 ft) made by a Rutgers University physics professor.⁵

The "Health and Safety Plan" in section 2.29.2 and Appendix P is an exercise in vagueness and promise, without substance, as is "Fire Safety Planning" in 2.29.3. "Ice shed" in section 2.29.5 does not provide for adequate protection for cars driving past turbines 500 ft. away. "Generally," this paragraph reads, "ice buildup slows a turbine's rotation and will be sensed by the turbine's control system, causing the turbine to shut down" (DEIS p. 2-185). "Generally" is not good enough, nor is reliance on a mechanical system without the back-up of adequate setback. There are no plans or preventive measures for lightning strikes or other significant accidents. The most important preventive measure, adequate setback, has not been taken.

Wind turbines themselves cause irregularities in the power supply as wind speed changes, including power surges as the wind gusts. Residents living near a new wind turbine installation in Meyersdale, PA, which came on line in December 2003, have had to replace stove elements and small appliances due to power surges which started at that time. Residents of Lincoln Township, WI, near a wind installation noticed an increase in lightning strikes in their area after the turbines went on-line in June 1999. Two computers protected by surge protectors and a TV set, all in different houses, were simultaneously "fried" one evening when lightning struck a nearby wind turbine tower.⁶

The DEIS does not discuss lightning precautions or data on lightning strikes from other installations. A search on the word "lightning" yields one hit, in Appendix P, with regard to performing a "risk analysis" and developing a safety plan sometime in the future. The time, however, is now, before permits are issued to allow construction.

4. Seismic activity

DEIS Section 2.1.3, in full:

"According to the USGS, which maintains records extending back to 1638 [sic], two significant earthquake epicenters (magnitude 5.0 or greater) have been recorded in the region. The Project Site is located within a low to moderately active seismic region. One magnitude 5.8 quake occurred in the Massena, New York area in 1944 and one quake with magnitude between 5.0 and 5.9 occurred South of Montreal, Quebec in 1877. Both areas are located between 50 and 100 miles from the Project Site. However, no earthquake epicenters with a magnitude of 6.0 or greater have been recorded within 100 miles (U.S. Geological Survey 2006). In addition, no significant tectonic faults have been mapped in

⁴ See photos at http://www.phase.com/wp/wind_turbine_photos.

⁵ Personal communication, Prof. Terry Matilsky, Dept. of Physics and Astronomy, Rutgers Univ., Piscataway, NJ.

⁶ Bituwer-Mackin, E. 2003. "Excerpts from the final report of the Township of Lincoln Wind Turbine Moratorium Committee." 12-4-03

Clinton County, and there are no known active faults (i.e., younger than 1.6 million years) in this region (USGS 2002)" (DEIS p. 2-2)

DEIS Section 2.2.3:

"As described in Section 2.1.3, the USGS states that one significant earthquake epicenter (magnitude 5.2) has been recorded within 50 miles of the Project Site and that the Project Site is not located within an active seismic region (U.S. Geological Survey 2001). No significant tectonic faults have been mapped in Clinton County, and there are no known active faults (i.e., younger than 1.6 million years) in this region (U.S. Geological Survey 2002)" (DEIS p. 2-7)

The DEIS preparers cannot even figure out what they themselves are saying in these two contradictory paragraphs and they did not do their homework.

An earthquake of magnitude 5.1 according to the USGS and 5.5 according to the Canadian Geological Survey with an epicenter 15 miles southwest of Plattsburgh occurred on April 20, 2002, at latitude 44.51 and longitude -73.66, 25 miles from the proposed project site. This earthquake was felt all over New York, New England (to Maine), and down to Maryland. Clinton and Essex Counties were declared federal disaster areas due to \$4.06 million worth of damage to roads, buildings, and wells.⁷

Dr. Frank Revetta, professor of earth science and geophysics at SUNY Potsdam and director of the Potsdam Seismic Network, states, "There is an east-west trending gravity high north of the Adirondacks in northern New York [which] correlates with a belt of earthquakes of shallow depth (<18 km). This is the most seismically active area in New York State."⁸

Small quakes of less than magnitude 4 are frequent in the region, including a 3.3 earthquake in Plattsburgh on 5/24/02, two 3.0 earthquakes with epicenters close to that of the larger 4/02 earthquake on 6/25/02 and 12/25/02, a 3.5 earthquake centered in Owl's Head on 4/8/03, and a 2.5 earthquake 3 miles west of the village of Malone on 3/3/05. An earthquake with magnitude 3.7 (4.1 according to the Canadian Geological Survey) occurred on January 9, 2006, just north of the Canadian border 5 miles from the village of Churubusco, NY, the location of Noble Environmental's Clinton Project, 12 miles from the Ellenburg Project, and 15 miles from Altona. "There is a belt of earthquakes that extends from the Adirondacks into Western Quebec," Professor Revetta said to the Plattsburgh Press-Republican. "You can expect earthquakes there quite frequently."⁹

It is unclear whether Noble Environmental's omission of this publicly available information was accidental and careless or deliberate and deceptive, but with regard to public safety neither type of oversight is acceptable. The proposed wind turbines are nearly 400 ft. tall. They are slender columns of tubular steel with a 60-ton nacelle and hub of the 40-ton propeller at 265 ft. The DEIS contains no data on the stability of industrial wind turbines in the presence of earthquakes despite a significant quake occurring 25 miles from the Altona Project site four years ago and frequent smaller quakes as close as 5 miles to other project sites. A 500-587 ft setback is not adequate to protect the public or leaseholders from harm should a structure of this weight, nearly 400 ft. tall, fall over. For reasons of public safety the

setbacks specified in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances must be revised. Construction cannot be permitted under these conditions

5. Noise and Noise-related Health Issues

The noise standards adopted in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances are wind turbine "industry standards." As such they make things easier on the operators of wind turbines by allowing more noise, but they do not comply with community noise standards promulgated by non-industry agencies such as the NYS DEC¹⁰ or the World Health Organization.¹¹

Compliance with NYS DEC noise standards (increasing the noise level no more than 6 dB over ambient) is anticipated to be almost non-existent near the Altona Project. "Sound pressure increases of more than 6 dBA over existing conditions will occur at most on and off-site residences" (DEIS, Section H, p. 3-9). This information is discussed only with regard to the fact that legally there does not need to be compliance with this standard because NYS DEC is not the lead agency. There is no plan to mitigate these noise effects. This represents a significant alteration in noise levels judged by state agency (DEC) standards and a significant change in community character, quietness being an important part the community character which leads people to build and live in rural areas.

In Lincoln Township, WI, a University of Wisconsin survey of residents near a 22 turbine installation in 2001, 2 years after construction, documented that 44% of residents 800 ft to ¼ mile from the turbines found noise to be a problem in their households, 52% ¼ to ½ mile away, 32% ½ to 1 mile away, and 4% 1 to 2 miles away. Under certain conditions the turbines could be heard up to 2 miles away.¹² These numbers correspond well to measurements made by Dr. GP van den Berg of the University of Groningen in the Netherlands near a more recent 30 MW, 17 wind turbine installation on the Dutch-German border, where residents living 500 m (1640 ft, or 0.31 mile) and more from the turbines were reacting strongly to the noise, and residents up to 1900 m (1.2 miles) away expressed annoyance.¹³

In a 2005 survey of 200 adult residents within ¼ mile of the French St. Crepin Windfarm, 83% responded. Of these, 27% considered the noise to be intolerable at night, 58% considered the noise to be disturbing, and 10% considered the noise to be disturbing by day. This is only a 6 turbine, 9 MW installation.¹⁴

Dr. van den Berg has now published his research as a book (his dissertation) which is available on-line at <http://dissertations.uh.rug.nl/faculties/science/2006/g.p.van.den.berg/>. Introductory and concluding chapters are reproduced in the accompanying material. His work focuses on figuring out why noise from wind turbines carries so much farther than expected and on developing new acoustic models based on known properties of the atmosphere to improve the current poor accuracy of acoustic modeling in

predicting how loudly and how far noise will carry from wind turbines. The introductory chapter provides an engaging, readable description of both the scientific and political aspects of the debate about wind turbine noise. Van den Berg's research also points to design features which could be incorporated into newer turbines which would both improve their efficiency and reduce the annoying types of noise they make.¹³

The audible noise produced by wind turbines has a thumping, pulsing character, especially at night, when it is louder. The noise is louder at night because of the contrast between the still, cool air at ground level and the steady stream of wind at the level of the turbine hubs, known as a "stable atmosphere" in which there is little vertical movement of air.¹⁴ This nighttime noise travels long distances. It has been documented to be disturbing to residents 1.2 miles away from wind turbines in regular rolling terrain,¹⁵ and 1.5 miles away in Appalachian valleys.¹⁶ Van den Berg documents how mountainous terrain can either lessen or increase the effect of a stable atmosphere in allowing sound to travel further.

At night, the WHO recommends, the level of continuous noise at the outside a dwelling should be 45 dB or less, and inside, 30 dB or less. The wind turbine noise at levels permitted by the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances are in the range of decibel levels which disturb sleep, even if permitted noise levels are not surpassed. Higher levels of noise disturb sleep and produce a host of effects on health, well-being, and productivity.¹⁷ These and other health effects of excessive community noise are documented in the WHO report with reference to scientific and medical literature. These include:

- For people to understand each other easily when talking, environmental noise levels should be 35 dB or less. For vulnerable groups (hearing impaired, elderly, children in the process of reading and language acquisition, foreign language speakers, and children with developmental disabilities) even lower background levels are needed. When noise interferes with speech comprehension, problems with concentration, fatigue, uncertainty, lack of self-confidence, irritation, misunderstandings, decreased work capacity, problems in human relations, and a number of stress reactions arise.¹⁸
- Effects of noise-induced sleep disturbance include fatigue, depressed mood or well-being, decreased performance, and increased use of sedatives or sleeping pills. Measured physiologic effects of noise during sleep are increased blood pressure and heart rate, changes in breathing pattern, and cardiac arrhythmias.¹⁹ Certain types of nighttime noise are especially bothersome, including noise which has impulses rather than being continuous, noise combined with physical vibration, noise with low-frequency components,²⁰ and sources in environments with low ambient

background noise²³ Children, the elderly, and people with preexisting illnesses, especially depression, are especially vulnerable to sleep disturbance.

- Noise has an adverse effect on performance over and above its effects on speech comprehension. The most strongly affected cognitive areas are reading, attention, problem solving, and memory. Children in school are adversely affected by noise, and it is the uncontrollability of noise, rather than its intensity, which is most critical. The effort to tune out the noise comes at the price of increased levels of stress hormones and elevation of resting blood pressure. The adverse effects are larger in children with lower school achievement.²⁴
- What is commonly referred to as noise "annoyance" is in fact a range of negative emotions, documented in people exposed to community noise, including anger, disappointment, dissatisfaction, withdrawal, helplessness, depression, anxiety, distraction, agitation, and exhaustion.²⁵ The percentage of highly annoyed people in a population starts to increase at 42 dB, and the percentage of moderately annoyed at 37 dB.²⁶

Participants in noise studies are selected from the general population and are usually adults. Vulnerable groups of people are underrepresented in studies, and if included, would show stronger effects at lower levels of noise. Vulnerable groups include the elderly, people who are sick or have chronic medical conditions, people with depression or other forms of mental illness, babies and young children in general, children with developmental disabilities, children dealing with complex cognitive tasks such as reading acquisition, and people who are blind or hearing impaired. These people may be less able to cope with the impacts of noise exposure and at greater risk for harmful effects than is documented in studies. Attention needs to be paid to them when developing noise setbacks requirements.

There are additional symptoms reported by neighbors of industrial wind turbine installations. Amanda Harry, MD, a British physician, found near a 16-turbine installation in 2003 that 13 out of 14 people surveyed reported an increase in headaches, and 10 reported sleep problems and anxiety. Other symptoms included migraine, nausea, dizziness, palpitations, stress, and depression.²⁷ Dr. Harry's study is in preparation for publication.

Many individual accounts from across the world support the same set of symptoms (in submitted material and clinical interviews I have performed as part of a study in progress). Based on accounts and interviews, and in discussion with Dr. Harry, I have defined the Wind Turbine Syndrome, a complex of symptoms which start when local turbines go into operation and resolve when the turbines are off or when the person is out of the area. The symptoms include:

- Sleep problems: audible noise or physical sensations of pulsation or pressure make it hard to go to sleep and cause frequent awakening.
- Headaches which are increased in frequency or severity.
- Dizziness, unsteadiness, and nausea.
- Exhaustion, anxiety, anger, irritability, and depression.

- ♦ Problems with concentration and learning
- ♦ Tinnitus (ringing in the ears).

Not everyone near turbines has these symptoms. This does not mean people are making them up; it means there are differences among people in susceptibility. These differences are known as risk factors. Defining risk factors and the proportion of people who get symptoms is the role of epidemiologic studies, which are in progress.

Chronic sleep disturbance is the most common symptom. Exhaustion, mood problems, and problems with concentration and learning are natural outcomes of poor sleep.

Sensitivity to low frequency noise is a potential risk factor. Some people sense low-frequency noise as pressure in the ears rather than heard as sound, or experience a feeling or vibration in the chest or throat.²⁴ Neighbors of industrial wind turbines describe the distressing sensation of having to breathe in sync with a rhythmic pulsation from the turbines which is not necessarily audible, especially at night when trying to sleep.²⁵

Preexisting migraine disorder is emerging as a risk factor for sensitivity to Wind Turbine Syndrome. Migraine is not just a bad headache, but rather a complex neurologic phenomenon that affects the visual, hearing, and balance systems and at times motor control and consciousness itself. Many people with migraine have increased sensitivity to noise and to motion – they get carsick as youngsters, seasick, or very sick on carnival rides. Migraine-associated vertigo (which is the spinning type of dizziness, often with nausea) is a described medical entity. Migraine occurs in 12% of Americans. It is a common, familial, inherited condition.

To keep our balance and feel steady in space, we use three types of input: from our eyes, from stretch receptors in joints and muscles, and from balance organs in the inner ear. At least two of these systems have to be working, and agreeing, to maintain balance. If the systems don't agree, as in seasickness or vertigo, one feels both ill and unsteady. Wind turbines impinge on this system via the visual disturbance of the moving blades and shadows, and, I hypothesize, by low-frequency air pressure waves impinging on the balance organs of the inner ear.

Goetz, "Promises gone with wind," *Scranton Times Tribune (PA)*, February 7, 2004.

Older people are may also be at increased risk for effects because of age-related problems with the function of the inner ear or the nerves and parts of the brain which receive signals from the inner ear. Many healthy people age 57 to 91 have such problems: 5% have chronic dizziness, and 24% tinnitus (ringing in the ears).³⁰ Older people often sleep less soundly and are more likely to have their sleep disturbed by noise.

Dizziness (specifically vertigo) and anxiety are neurologically linked phenomena,³¹ so the anxiety and depression seen in association with other symptoms near wind installations are not necessarily an emotional response to symptoms, but may be a neurologically linked response to the balance disturbances themselves. Sleep deprivation also causes anxiety and depression.

Industrial wind turbines produce low-frequency as well as audible noise. Dr. Oguz Soysal, Professor and Chairman of the Dept. of Physics and Engineering at Frostburg State University in Maryland, measured sound levels over half a mile away from the 20 turbine wind farm in Meyersdale, PA, in 2005. Audible (A-weighted) dB (decibel) levels were in the 50-60 range, and audible plus low-frequency (C-weighted) dB were in the 65-70 range.³² A difference of 10 dB between A and C weighting represents a significant amount of low-frequency noise by World Health Organization standards.³³ Dr. van den Berg measured wind turbine sound spectra 750 m (0.47 mile) from a 17 turbine installation in 2002. His graphs reveal dB levels averaging 68-90 dB in the frequency range less than 10 Hz, and over 60 dB in the 10-100 Hz frequency range.³⁴ Van den Berg states in his dissertation, "I agreed with delegate Jorgen Jakobsen, who presented a paper on low frequency wind turbine noise [Jakobsen 2004], that even though wind turbines did produce an appreciable amount of infrasound, the level was so far below the average human hearing threshold that it could not be a large scale problem"³⁵ (emphasis added).

Dr. van den Berg shares the perception common in both the medical and acoustic fields that if you can't hear a noise, it can't affect you, but the world's leading researchers in the health effects of low-frequency noise exposure, Nuno Castelo Branco, MD (Head of the Scientific Board, Center for Human Performance, Alverca, Portugal, and Principal Investigator for the Vibroacoustic Disease Project supported by the Portuguese Ministry of Science and Technology) and Mariana Alves-Pereira (a biomedical engineer at the New University of Lisbon) do not agree.

This international research group, centered in Portugal and including physicians from Poland, Russia, and the United States, has published extensively on the effects of low-frequency noise on parts of the body other than the ears, particularly on the cardiovascular, pulmonary, and neurologic systems.³⁶ The

research, ongoing since the late 1980's, includes clinical, pathological, and experimental (animal model) investigations. The entity these physicians and PhD's describe, called **Vibroacoustic Disease (VAD)**, includes fibrosis (laying down of additional fibrous thickening in the form of collagen) in the cardiovascular and pulmonary systems and seizures and cognitive changes in the brain. The disease is caused by long-term exposure to low-frequency noise (less than 500 Hz), most of which cannot be heard.

Just as we cannot detect X rays (because our eyes are not sensitive to this frequency) yet can be harmed by them, so we can be harmed by non-audible noise (pressure waves in the air), though our ears are not sensitive to them. The mechanism of this harm is the differing resonance frequencies of different parts of the human body, especially the chest and skull. Air pressure (sound) waves of certain wavelengths resonate inside these walled spaces, setting up vibrations to which the body responds by reinforcing its softer tissues with extra collagen, causing such problems as thickening of the pericardium (membrane inside which the heart beats) and cardiac valves, fibrosis of the lungs, and proliferation of glial (supporting) cells in the brain.

Vibroacoustic disease has been studied mostly in aviation workers (including pilots, flight attendants, and technicians) but is also found in other industries and community settings. One of the researchers, Mariana Alves-Pereira, a biomedical engineer, has recently compared the noise spectrum of an environment known to predispose occupants to VAD - the cockpit of a commercial jetliner - to the noise spectra of other common community settings. She finds that a variety of community settings have the low-frequency noise potential for causing VAD. She has examined noise measurements of industrial wind turbines provided to her by Amanda Harry, MD, and her collaborating acoustician, Dr. Manley in England and found the low frequency noise intensities to be in the range which can cause VAD, especially given prolonged in-home and overnight exposures. Alves-Pereira has also examined graphs of wind turbine sound pressure levels vs. frequency measured by van den Berg and considers the noise intensities at the lower frequencies to be concerning with regard to their potential for causing VAD. She is aware of the symptomatology of the d'Entremont family in Pubnico, Nova Scotia, who had to move out of their home 1000 ft. from a wind turbine, and notes the similarity of their symptoms to those of people with pathologically proven VAD. Part of our research in progress is to provide Alves-Pereira with additional wind turbine noise measurements.

Alves-Pereira has helped clarify how neighbors and town governments should be handling noise measurements related to wind turbines. An A-weighted decibel measurement misses all the low-frequency noise, since A weighting is designed to mimic the frequency response pattern of the human ear and screens out low-frequency noise. Rather than a single measurement of loudness, noise needs to be characterized by measurement of linear (unweighted) decibel levels in 1/3 octave bands across the sound frequency spectrum. Measurements should be taken inside homes, since the longer wavelengths in low-frequency noise resonate within rooms, magnifying their loudness relative to the outside. Low frequency noise also comes through walls with less attenuation than the 15 dB decrease assumed for audible noise.

Noble Environmental's analysis of noise impacts in this DEIS was technically inadequate with regard to current knowledge. Specifically:

- Ambient noise levels were not measured (Appendix H, Section 3.4, p. 3-3). Assumed rural background noise levels are too high, especially for nighttime, the critical time for noise
- Sound intensity decreases with distance in complex ways depending on the frequency of the sound (low-frequency sound carries further and passes obstructions with less attenuation), the stability of the atmosphere (turbine noise carries further in a stable atmosphere as occurs at night), and the presence of reflective surfaces (increased propagation across open or frozen lakes or in the presence of a temperature inversion providing a reflective atmospheric layer). The discussion

- of sound propagation on p. 3-3 of Appendix H is oversimplified and allows for underestimation of the distances to which turbine noise is predicted to be propagated
- Modeling of sound transmission did not look at the worst case scenario of the nighttime stable atmosphere, and thus underestimated the amount of noise likely to occur at various distances from the turbine installation at night, the critical time in terms of disturbance and health effects. Dr. Leventhall, the project acoustics consultant, is aware of these more accurate models of sound propagation from wind turbines but did not require them to be used in the modeling, showing negligence in his function as a technical consultant.
 - The statement on p. 3-9, "Nor would use of alternative equipment further reduce sound levels," may apply to equipment which can be purchased right now but not to equipment which may be designed in the near future to vary blade pitch during rotation as recommended by van den Berg to reduce or eliminate the nighttime thumping which develops in stable atmosphere.³⁷ There is a rush to build because the developer stands to make a lot of money, while from the point of view of community sustainability of this type of development it would make sense to wait a few years until equipment which solves the nighttime noise problem is available.
 - The measurement of wind turbine noise at Fenner Wind Farm to screen for low frequency noise occurred over a 17 minute period during the day, though van den Berg points out that to eliminate the interference of wind blowing on the microphone (which can confuse the issue of whether there is low frequency noise) it is better to measure at night under conditions of atmospheric stability (little to no wind at ground level, substantial wind at turbine hub height).
 - The acoustic weighting network (or lack of a weighting network) used for the Fenner noise sample was not specified.
 - Dr. Leventhall, the Project consultant, dismisses the low-frequency noise documented in this measurement [note rise in dB level on the left, low-frequency sides of the graphs] as irrelevant for two reasons: 1) interference due to microphone noise, and 2) below range of human hearing. Point (1) could be corrected by measuring at another time of day/atmospheric condition, and (2) is contradicted by the research on vibroacoustic disease. Dr. Leventhall does not go so far as to say that there is no low-frequency noise, just that it is "not unusual," in which he is accurate. Wind turbines in general produce low-frequency noise,³⁸ which is a problem elsewhere and is likely to be a problem here, too.

In summary, this Project has substantial potential for adverse noise effects on neighboring residents for which adequate studies have not been performed nor realistic mitigation proposed. Noise impact analysis was performed in a superficial fashion ignoring current knowledge so as to bias results in favor of the developers. Realistic mitigation with current technology means adequate setback. The Academy of Medicine of France has recommended a 1.5 km (0.96 mile) setback because of noise and health issues;³⁹ ours should be at least this. Delaying the Project until the technology is available for varying of blade pitch to increase efficiency and decrease noise would also be appropriate

6. Shadow flicker

When turning with the sun behind them, turbine blades cast moving shadows across the landscape and houses, creating as a strobe effect within houses which can be difficult to block out. Some people lose their balance or become nauseated when they see the movement of shadows or the movement of the huge

³⁷ van den Berg, GP. 2006. "Sound of high winds."

³⁸ *ibid*, p. 4-5

³⁹ Chouard, Claude-Henri. 2006. <<Le retentissement du fonctionnement des éoliennes sur la santé de l'homme>> ("The repercussions of wind turbine functioning on human health"), Academie Nationale de Medicine (French National Academy of Medicine)

blades themselves. As with car or sea sickness, such symptoms occur when the three organs of position and movement perception (the inner ear, eyes, and stretch receptors in muscles and joints) do not agree with each other: the eyes perceive movement while the ears and stretch receptors do not. People with a personal or family history of migraine, or migraine-associated phenomena such as car sickness or vertigo, are more susceptible to these effects. The strobe effect also has the potential, like other flashing lights, to trigger seizures in people with epilepsy.

In Lincoln Township, WI, two years after installation of 22 industrial wind turbines, 33% of residents 800 ft to ¼ mile from the turbines found shadows from the blades to be a problem, 40% ¼ to ½ mile away, 18% ½ to 1 mile away, and 3% 1 to 2 miles away.⁴⁰

Forty-two houses will be subjected to shadow flicker from the Altona Project (DEIS Appendix G, p. 5-2). Proposed mitigation will mostly require people to stay inside behind their blinds, which are known not to work to keep out the shadow flicker (DEIS Appendix G, p. 5-7). The only realistic form of mitigation is setback, which is inadequate under Altona municipal law. From the Lincoln Township data, setback of at least one mile is needed.

7. Birds and bats

The federal government is concerned enough about the potential wildlife mortality due to wide scale development of wind turbines that the GAO (Government Accountability Office) issued a lengthy report in September 2005⁴¹ and the National Academy of Sciences commissioned a 20-month study whose period does not end until December 2006:

"The National Academies will establish an expert committee of approximately 14 members to carry out a scientific study of the environmental impacts of wind-energy projects, focusing on the Mid-Atlantic Highlands as a case example. The study will consider adverse and beneficial effects, including impacts on landscapes, viewsheds, wildlife, habitats, water resources, air pollution, greenhouse gases, materials-acquisition costs, and other impacts. Using information from wind-power projects proposed or in place in the Mid-Atlantic Highlands and other regions as appropriate, the committee will develop an analytical framework for evaluating those effects that can inform siting decisions for wind energy projects. The study also will identify major areas of research and development needed to better understand the environmental impacts of wind-energy projects and reduce or mitigate negative environmental effects. The approximate starting date for the project is April 21, 2005. A pre-publication report will be issued at the end of the project in December, 2006."⁴²

I refer below to a letter to Patrick McCarthy at Ecology and Environment from David Stilwell, Field Supervisor, US Fish & Wildlife Service, dated May 13, 2005.⁴³ This letter is appended to the Environmental Assessment Form on the Noble Environmental website at:

Since Noble Environmental locked its website against printing (despite their avowed commitment to "transparency"), the attached reproduction is reduced in size and blurred but still legible. The original may be viewed on the website.

Under *Recommendations* in the above letter (Stilwell to McCarthy, 5-13-05), the USFWS states, "Pre-construction studies of bats for this location are recommended. These studies should be of sufficient rigor to determine the temporal and spatial distribution of resident and migrating bat and bird species in and adjacent to the project area during various weather conditions (e.g. fog, rain, low cloud ceilings, clear skies, etc.)" Further, "In order to determine the potential collision-hazard for a particular site, and to account for annual variability, the spatial and temporal uses of the project airspace by birds and bats need to be defined during a multi-year period. This can best be accomplished by using remote sensing technology (radar, acoustic, and infrared) to collect data in various spatial and temporal scales (day and night, season to season, and year to year). Traditional sampling protocols (e.g. visual observation and/or mist netting) may be appropriate to supplement the remote sensing work and would likely be necessary to ground truth the data for individual species. Survey techniques are currently evolving and the project sponsor should work closely with this office and the New York State Department of Environmental Conservation (NYSDEC) to develop a draft study design prior to conducting any studies. Survey results should also be submitted to us for review and comment, along with proposed project-specific avoidance and minimization methods to reduce the risk of bat and bird mortality."

Multi-year studies were not done. Results have not been submitted to USFWS for review. Of note, too, is that David Stilwell, Field Supervisor, USFWS, who wrote the above-reference letter to Noble Environmental, strongly criticized the Avian Risk Assessment (ARA) created by the same environmental consultants, Ecology and Environment, Inc., of Lancaster, NY, for the Chautauqua Wind Project in Chautauqua, NY.⁴⁴ Many of the critiques leveled at the Chautauqua ARA apply to the ARA in the DEIS for Ellenburg, Clinton, and Altona. These include the need for multi-year studies of bird and bat migration (because of the variability in migration timing and location with wind and weather patterns noted within years and year to year), the limitations of mobile radar in detecting small migrating birds and bats, and the role in observer effort in getting realistic information even about the presence of particular species, especially the more critical rare species. As for Chautauqua, there is no data in the ARA for Ellenburg, Clinton, and Altona which pertains to population densities or numbers, yet this is the critical information to have if we are going to be able to assess, in future, the effects of large-scale industrial wind power development on bird and bat populations.

I contacted Timothy Sullivan, the biologist at USFWS in Cortland, NY, (607-753-9334) responsible for the Noble projects in Clinton County, on May 30, 2006. He would like to review the ARA for Ellenburg, Clinton, and Altona as his supervisor, David Stilwell, indicated in his letter of May 13, 2005 would be appropriate, but has not had the time to do this given other responsibilities and the many wind projects under development in NYS. The intensity of development right now, in other words, is undermining our governmental oversight procedures. As I am, he is concerned that the cumulative effect of multiple industrial wind power installations in or just above the St. Lawrence River Valley will have a negative impact on migratory birds of a variety of types. Passerine or songbirds are in a general state of population decline related to the cumulative effects of many insults, including habitat destruction, fragmentation, and

⁴³ David Stilwell, USFWS Field Supervisor, Letter to Patrick McCarthy dated 5-13-05.

⁴⁴ David Stilwell (signatory) and Timothy Sullivan (biologist), October 12, 2005, "Comments on our review of 2004 Avian Risk Assessment Report, Chautauqua Wind Project."

loss of quality, impacts with buildings, cell towers, power lines, and other tall objects; and cats and cowbirds (predator accessibility related to habitat fragmentation).

With regard to birds, sensitive species in or near the project area include the Bald Eagle (threatened in NYS), Northern Harrier (a large open-country hawk, threatened in NYS), Pied-Billed Grebe (a small waterfowl, threatened in NYS), Sedge Wren (a wetland species, threatened in NYS), Bicknell's Thrush (a rare eastern thrush, imperiled in NYS), and Common Loon (vulnerable in NYS). Other birds common to our area and on the NYS "Species of special concern" list are Cooper's and Sharp-shinned hawks, Northern Goshawk, Osprey, and American Bittern.

The DEIS description of where Snow Geese occur is inaccurate. Snow Geese use farmlands at least as far west as Malone and east to Lake Champlain in a broad front which is expanding year by year. In fact, we are located in the only flyway (and stop-over, for replenishing energy reserves) of the Greater Snow Goose in the world⁴⁵. Snow geese spend the month of November and most of December here; Canada Geese arrive earlier and disappear about the same time. Geese and other waterfowl use as part of their migratory pathway extensive wetlands along the St. Lawrence River in Quebec. Just over the border from Fort Covington (Franklin County) is the Réserve nationale de faune du lac Saint-François, "created mainly to protect exceptional wetland habitat on the shores of Lac Saint-François that is used by a variety of aquatic and land birds and shelters a number of rare animal and plant species" (website of the Canadian Wildlife Service).

Ground surveys for spring "migratory" birds were done on only May 25 and 26, 2005, though bird migration through our area runs from late March to late May or so; timing and intensity varies year to year. The birds detected were local breeders, but most of the species detected at this time locally are migrant species which winter elsewhere and fall under the Migratory Bird Act. The methodology used - fine-minute detection periods by seeing or hearing - is an adaptation of the Breeding Bird Survey technique which has no applicability in this situation, and serves only to limit, by extreme limitation of observer effort, the numbers of species detected. There is no attempt made to estimate population numbers or density in any way. The similar technique used for the Breeding Bird Surveys in early and late June, 2005, with 3-minute detection periods, is also inadequate to obtain data on population sizes. This technique was developed to have a uniform way to get simple, limited data from disparate untrained observers across the country. It is not a recognized way of estimating bird population densities or numbers (see references⁴⁶ for discussion).

Bat methodology was limited to visual nighttime monitoring in a beam of infrared light and use of bat call detector devices. Very small numbers of bats were detected in the beams. The preparers of the DEIS discuss how the visual and radar data were not similar, so dissimilar that they considered these two forms of measurement to be "independent," though of course they were not independent since they were measuring the same phenomenon (birds and bats flying overhead) at the same time; the unrelatedness of the data obtained reflects measurement problems, not "independence" of data sets. At any rate, the visual studies do not allow one to calculate the proportion of "targets" in the radar study which were bats and birds because the two sets of measurements were so different they did not seem to reflect the same nightly phenomenon. The call detector devices were mounted on silos in farmland, and allowed identification of

four species between the two sites. As for bird migrant studies, limitation of effort limited the numbers of species detected and no data was collected on population densities or numbers.

Discussion of bat impacts does not reflect findings of large bat kills by wind turbines on Appalachian ridges and the correlation of bat kill with a generating vs. non-generating spinning turbine blade.⁴⁵

Comparisons of numbers such as rates of radar target objects picked up at the different wind plant sites surveyed is meaningless without statistical analysis, since even superficial inspection of the data presented in the graphs in the radar monitoring study show wide variability day to day. When data is variable, it is more likely that average values pulled from such data sets do not differ from each other. This is a most basic concept in statistics which is ignored in the data presentation in the ARA. It is also unclear what point the preparers were trying to make in presenting such comparisons.

To provide references and discussion of adequate migratory bird monitoring, the USFWS comment on the Chautauqua Wind Project DEIS is attached. The sites are different but the methodologic inadequacies are the same, produced by the same contractor, Ecology and Environment.⁴⁶

In summary, there has not been adequate oversight of wind power development proposals by USFWS due to the agency being overwhelmed by the number of such proposals in the state, yet such oversight and coordination of bird and bat population issues across broad geographic fronts is badly needed, as recognized by the initiation of two federal level agency studies in the last year which focus on wildlife issues. The current Project needs to be delayed for such review to take place, and to bring the bird and bat studies closer to compliance with USFWS recommendations by having the developers sponsor at least another year of wildlife studies. USFWS oversight to bring the studies methodologically closer to usefulness, in terms of obtaining population data, is recommended.

8. Non-avian wildlife

With regard to terrestrial and aquatic wildlife, information in the DEIS is thin and suggests both incompetence and lack of effort. Habitat and foraging requirements of the White-tailed deer and Black bear are described with mention that suitable habitat occurs within the Project Area, but population estimates are notably lacking. Pre-construction deer and bear population counts by methods well known to wildlife biologists would be appropriate to allow post-construction comparisons. Without this data, the effects of wind turbine construction on game species cannot be assessed. To my knowledge before and after population comparisons have not been done for other wind turbine projects in New York State or adjacent states, though hunting is a major recreational activity in rural areas and resident accounts from other wind turbine sites report relative scarcity of deer after construction. This project is the second large windplant proposed for NY State, the first being the Tug Hill Project (120 turbines) built last summer. Many additional projects are in the planning stages. Given SEQRA's focus on cumulative effects, I strongly recommend that before further projects go into construction, including this one, that wildlife

See reports by Merlin Tuttle, Greg Johnson, Edward B. Arnett, Wally Erickson, Jessica Kerns, Brian Cooper, and Jason Horn. See Edward B. Arnett (Bat Conservation International), Letter regarding wind company distortion of bat research, June 5, 2005.

⁴⁶ David Stilwell (signatory) and Timothy Sullivan (biologist), October 12, 2005, "Comments on our review of 2004 Avian Risk Assessment Report, Chautauqua Wind Project."

biologists controlled by NYSDEC obtain two years' worth of population data on significant game species to allow valid post-construction comparisons, and that turbine complexes not be built across a wide area until post-construction data is available for a limited number of sites.

In the DEIS, further discussion of mammals and other vertebrates is relegated to Table 2.9-1, a list by habitat. This table misses even common species such as red squirrel, weasel species, mink, marten, fisher, otter, red fox, coyote, woodchuck, voles, mice, snowshoe hare, etc., which are common in our Adirondack foothills area, showing insufficient care and effort on the part of the preparers of the DEIS. Population data is again lacking. There is no mention of large predators with large home ranges which may include the project area, including cougar which are regularly seen from Altona into St. Lawrence County, including a video of a cougar with a cub filmed in northern Franklin County in 2003. The cougar is a federal endangered species officially considered to be extirpated in NY State, though it does occur and apparently breeds. Other large mammals of which there are reports in the area include bobcat, wolverine, wolf (also a federal endangered species considered extirpated in NY State), and moose. These species are not considered.

Existing research on the effects of wind turbines on wildlife is not mentioned. Lawrence Rabin, Presidential Management Fellow in the US Forest Service R&D in Washington, DC compared the behavior of two groups of California ground squirrels in similar environments, one close to wind turbines and the other not. To be published in a forthcoming issue of *Biological Conservation*, the study found that squirrels near turbines were more likely to dash back to their burrows when hearing an alarm call and spent more time looking around for predators. A possible reason for the squirrels' increased alertness is their need to compensate for their reduced ability to communicate through sound. Both behaviors can reduce reproductive success by reducing foraging time and increasing energy expenditure, and have the potential to be shared by a number of animal species.⁴⁹

The discussion of the potential impacts of the project on terrestrial wildlife is, like the discussion of wetlands, an account of inevitabilities and minimization without real content, including the failure to acknowledge the significance of potential impacts. Statements such as:

"Although this will result in a local reduction in the amount of available forest habitat, the total acreage is minor in comparison with the overall acreage of forested land located in the Project Area." (DEIS p. 2-83)

ignore the issue of cumulative effect highlighted by SEQRA. The authors conclude soothingly, "Indirect impacts on wildlife will occur as a result of habitat alteration in association with construction and operation of the Project. However, these impacts are not expected to be significant" (DEIS p. 2-84), having presented no population data, no before-and-after wildlife population figures from other sites, nor even demonstrated basic competence in the wildlife field by presenting an accurate mammal list.

9. Wetlands

Ecology and Environment's disregard or perhaps ignorance of ecological principals is apparent throughout the DEIS, starting with the Executive Summary: "The loss of wetlands will be compensated for by the construction of new wetlands in the same watershed" (DEIS p. 2). An engineer or a backhoe operator can construct a wet place but not a wetland; wetlands have to regenerate and during regeneration will not support the same communities of plants, insects, invertebrates, fish, amphibians, birds, and mammals as they did before they were disturbed. The type of wetland which regenerates depends on soil

⁴⁹ "Wind turbines send wildlife diving for cover," *New Scientist*, Issue 2549, May 3, 2006, p. 18.

type, siltation properties, water flow, and the presence of beaver, and has a specific time course. These issues are given no consideration

The sections of the DEIS on wetlands, particularly the Wetland Delineation Report in Appendix D, presents a variety of maps and detailed descriptions of methodology and the vegetation of different wetland areas within the project area, but does nothing significant with the information. The language used minimizes the importance, "functional value," and size of the various wetlands, and tells us soothingly that "Project facilities have been sited to minimize or avoid wetland impacts to the greatest extent practicable, while still being able to meet the Project objectives" (DEIS Section E, p. 7-2). We are being told that wetlands are not important. The possibility of siting changes during construction is left open and uncontrolled. "However, until the individual turbine sites are designed and the final grade contours are established, it is not possible to determine the actual extent of wetland impacts within the turbine sites" (DEIS Section E, p. 7-7). Mitigation plans are vague: "If avoidance of drainages and swales is not possible, the turbine site will be designed in such a way to allow for the continuation of the surface flow" (DEIS Section E, p. 7-5). Adjacent sentences contain conflicting, vague information: "No significant impacts are expected to streams in the Project Area as a result of construction or operation of the Ellenburg Windpark. Potential indirect impacts may result from construction activities, including increased sedimentation and turbidity caused by increased surface runoff from work areas" (DEIS Section E, p. 7-10).

The USACE has jurisdiction over all wetlands and waterways in the United States, regardless of size, which are connected hydrologically to a navigable waterway. This could be a marsh connected to a ditch to a stream to a river which eventually flows into the St. Lawrence River or other navigable waterway.

The USACE will not issue permits to place turbines in wetlands, because turbines don't need to be in wetlands and can be placed elsewhere. However, they issue permits (and require permits) for all crossing of waterways and wetlands in their jurisdiction by roads or power lines.

I spoke on May 31, 2006, with Kevin Bruce in the Albany Field Office of the US Army Corps of Engineers, 1 Bond St., Troy, NY 12180. 518-273-7420, fax 518-273-2055.

The USACE has received applications for all three Noble projects. Mr. Bruce said they are early in the process of reviewing the application for the Clinton project, and that review of the Ellenburg and Altona projects has not yet started. He is planning a site meeting in the 3rd week of June for the Clinton project.

Mr. Bruce told me he commonly is asked by project sponsors if they can go ahead and start constructing roads or break ground in areas of dry land not under the jurisdiction of the USACE before securing permits from the USACE. The USACE generally advises project sponsors not to do this, since the USACE might request changes in the project to avoid wetlands, including by access roads or power lines.

USACE review, which falls under the Clean Water Act and the National Environmental Policy Act, also triggers federal level review under the Fish and Wildlife Coordination Act and the National Historic Preservation Act.

In summary, it appears that extensive federal level review of the three Noble projects is still in the early stages. It would not be appropriate for the town boards, as the lead agencies, to issue building permits without certifying that the appropriate federal review processes have been completed and the required permits obtained, nor for Noble to proceed with construction without required federal permits.

It is not at all clear from the DEIS that state or federal law will be upheld in the Ellenburg Project with regard to wetlands. Because of the vagueness and apparent project dominance of decisions being made

with regard to wetlands, on-site NYSDEC and federal (USACE) oversight will be critical to modify turbine placement decisions during the project planning phase, to oversee them (to prevent changes) during the construction phase, and to oversee other mitigation measures.

Cornell Studies Pros, Cons to Wind Power
March 17, 2005
by Vanessa Hoffman
Sun Senior Writer
Cornell Daily Sun

Wind and snow are two of the major components of Ithacan winters. Cornell is currently studying how to harness the power of the former to provide energy for up to 10 percent of the University's electricity.

In the fall of 2003, members of KyotoNOW! made a presentation proposing that the administration explore the possibility of wind power; the University subsequently agreed to conduct a feasibility study.

→ The Cornell Department of Utilities and Energy then conducted a wind inventory study, which looked at a 15-mile radius around Ithaca and determined the Mount Pleasant hilltop to be the best location for wind turbines. This Cornell-owned site is about ten miles from central campus and also houses the Harthung-Boothroyd Observatory and WBCU transmission tower. Cornell has decided to install a temporary 50-meter meteorological station on Mt. Pleasant to take actual wind data and see if it matches up with the data based on windmaps and predictions.

"We're really in a very preliminary and exploratory phase of any potential wind project," said Harold "Hal" Craft '61, vice president for the administration and chief financial officer.

The Kyoto Task Team, created by Craft in 2001, has also been involved in the

effort, corresponding with its goal to hold Cornell to its commitment to seek to reduce greenhouse gas emissions as stated by the Kyoto Protocol.

"The preliminary studies were looking at if we should continue with a larger study and if it's economically and physically feasible," said Andrew Schatz '05, a member of the Kyoto Task Team.

William "Lanny" Joyce, manager of engineering, planning and energy management in the department of utilities and energy, said that the team is looking at up to eight windmills, on the two ridges at Mt. Pleasant hilltop, each centered 80 meters off the ground and having 40 meter long blades.

"It would not only benefit the environment, but also the University, because wind is a renewable resource. Cornell can set a precedent because not too many universities have taken on an endeavor like this; it shows that they really care about the future of the world," said KyotoNOW! president Jeanne Kopun '06.

She said that last year, KyotoNOW! visited Fenner Wind Farm in Madison County, N.Y., to ask questions and address concerns about wind power. The proposed wind turbines for the Mt. Pleasant site would approximately half the size of those at Fenner Wind Farm, according to Prof. Norman Scott, biological and environmental engineering, and member of the Kyoto Task Team. Kopun said that KyotoNOW! members found that the wind turbines were not noisy or ugly, and there were no reported bird or bat deaths.

According to Scott Sutcliffe, associate director of the lab of ornithology, "The Lab of Ornithology conservation director, Ken Rosenberg, is designing a study to evaluate the site, its resident and migratory birds, and the potential affect a windfarm would have upon bird populations."

"There's no 'no-impact' solution for the creation and use of energy," Joyce said.

Last week, 20 residents in the immediate area of the proposed site brought a petition to the Dryden Town Board, asking the board to study any proposal very carefully and change the zoning law specifically to not allow industrial wind farms. The petition states the residents' concerns as: turbine noise, visual impacts, strobing effects, nighttime flashing of FAA-mandated lights, decline in property values, bird and bat deaths, threats to air traffic to and from Tompkins County Airport and quality of life effects due to proximity to wind turbines.

"Basically, we want Cornell to take things really, really slowly because we think that there are bad environmental, health and quality of life and animal impacts" said Stuart Davis, senior lecturer, english, and resident in the immediate area.

He added, "This isn't a NIMBY thing, this is NIABY, 'not in anyone's backyard.' I would not wish it on anyone unless it is safe and efficacious."

The residents gave materials to the board, including testimonials from people who have lived near wind turbines.

"It's been eye-opening for me to go from the position of a student thinking it would be great if Cornell looked into wind energy to now being paid by local taxpayers in Dryden and being responsible for their well-being. You have to take a good, hard look at the positives and negatives," said Debbie Gross, environmental planner for the Town of Dryden Advisory Council.

She said that Cornell would need a permit from the Building and Zoning Office to built the wind turbines and due to current zoning regulations, the University would have to apply for a zoning variance or work with the town to draft a new ordinance.

"For any wind farm, there is always a huge amount of public opposition. A lot of people don't want to look at them; I personally find them beautiful," said Abby Krich '04, member of the Kyoto Task Team and former KyotoNOW! president.

Last year the New York State Public Service Commission adopted a renewable portfolio standard and a policy increasing to at least 25 percent the electricity used by New York State consumers obtained from renewable resources. According to Joyce, Cornell's electricity energy is "13 percent from the campus cogeneration system, which makes electricity as a byproduct of heating the campus, 2 percent from the hydroplant in Fall Creek, and the remaining 85 percent from NYSEG, our local utility company." NYSEG partnered with Community Energy, Inc about three years ago, said Paul Copleman, manager of customer service at Community Energy, Inc. He said that the wind energy supplied to upstate New York comes primarily from Wyoming County and the Fenner Wind Farm in Madison County.

Environmental 'Father Figure' Blames Peers For Wrecking the Environment

Top environmental scientist James Lovelock rejects renewables as a means to solve the energy crisis, believing they will do more harm than good. He tells StockInterview.com that he believes environmentalists are damaging the environment instead of saving it.

May 25, 2006 in [eMediawire](#)

SARASOTA, FL. (PRWEB) May 25, 2006 -- Leading environmental scientist James Lovelock blames fellow environmentalists for damaging the environment with renewable energy solutions, while claiming to save it. Lovelock told StockInterview.com, "Their solutions are basically urban-political solutions. It's mostly made up of urban people, who know almost nothing about the countryside and still less about the ecosystem."

Lovelock scoffed at their embrace of renewable energy sources, saying, "They are being very foolish. They are living in a dream world." Instead, the atmospheric scientist and bestselling author actively advocates adding more nuclear energy as a solution to the energy crisis, saying, "There is no sensible alternative to nuclear power if we are to sustain civilization."

Best known for his Gaia Theory, Lovelock's bylined articles in Reader's Digest (March 2005) and London's Independent newspaper strongly urged other environmentalists to follow his lead in endorsing nuclear power. His recent book, *The Revenge of Gaia*, which discusses the current energy crisis, has caused a stir in

Neighbors complain of wind farm nuisances

By Scripps Howard News Service
April 28, 2006

Robert ADVEE

Search site

AP BUSINESS

The idea of windmills brings to mind bucolic Renaissance paintings of Dutch landscapes and tulip beds.

But that's hardly the experience of some who live next to the 400-foot electricity-generating giants being built across America's breezy plains.

They complain about the incessant "whoosh-whoosh-whoosh" of the machines at work, the flashes of light and shade across their windows, and the occasional terrifying midnight screech of turbines repositioning themselves to catch shifting winds.

"It sounds like a train going through, except the train never comes through," said Wayne Danley, whose life had been turned upside down by a giant windmill located 900 feet from his house in rural Fenner, N.Y., where he has lived since 1976.

Danley said he fears the days when the winds come from the northwest. "The whoop, whoop, whoop becomes a roar," he said. And in the spring before the trees sprout leaves, the turning turbine causes flashes of light in his living room that so annoyed his wife, the pastor of a local church, that she had to flee to the bedroom to get away from it.

Danley said he has nothing against windmills on the neighboring wind farm. He only wishes someone would do something about

HOME

relocating the one on his doorstep. "It's too close," he said.

While the industry portrays electricity-generating windmills as a benign and natural source of power, community opposition to new windmill farms is cropping up across the country - particularly in Eastern states, where there are more people fleeing urban blight to live in idyllic rural towns.

Last week, authorities in Vermont rejected plans for a windmill farm on top of that state's scenic mountains near East Haven, while Peru, N.Y., declared a one-year moratorium on any construction of windmills so the town can further study the impact on the rustic charm of the Adirondacks.

Community activists in Dryden, N.Y., last year forced Cornell University to withdraw plans for a windmill farm in their tiny community, and in England - where opponents have ridiculed the huge machines as "lavatory brushes in the sky" - lawmakers are considering proposals that would require any new windmills to be located no closer than two miles from homes, and preferably out of sight.

John Semmler, an education consultant who has lived in Dryden for 30 years, said he's been ridiculed as being a NIMBY - meaning "not in my backyard" - for his role in leading the opposition to the Cornell project. Semmler and other residents argued that if Cornell wanted to build an industrial complex of windmills, it could easily do so next to the Ithaca campus eight miles from Dryden and leave their vistas and peace undisturbed.

"I'm not a NIMBY, I'm a NAMBY - 'not in anybody's backyard,'" said Semmler, who toured other wind farms in the region to find out how they have affected people's lives. "I resent the use of the word 'wind farm' to describe these projects - these are huge, monstrous pieces of machinery that make noise," he said.

The industry did not expect the intensity of community opposition that wind farms are getting, said Marion Trieste, publicist for the Alliance for Clean Energy New York, an organization that has the backing of industry and environmental groups.

"There's a lot of misinformation, and a lot of inflamed discussion about negative encroachment," she said.

Trieste said supporters of wind energy outnumber opponents. The group has put a video of testimonials from people living under windmills who enthuse about their experience with the machines, and the contributions windmills make to renewable energy.

"People are passionately concerned about their communities, and concerned about energy, and we have to come to terms with the alternatives," she said.

The American Wind Energy Association, which represents the industry, says it knows of only a few complaints about noise. Scores of new facilities are set for construction under incentives for wind energy that Congress included in last year's energy bill. The incentives expire in 2007.

"You can stand under a wind turbine and have a normal conversation," said Laurie Jodziewicz, a policy specialist for the association. "It's just a 'whoosh.' "

Jodziewicz said modern turbines are much quieter than the first generation of windmills, and that complaints about wind farms today "are very, very rare." She said there have been complaints about the strobe-light effects, but those occur only during certain months of the year and depend on the sun's angle to the turbine blades.

Robert Larivee, a professor of chemistry at Frostburg State University in Maryland, says that's not his experience. He and his family have lived for the last three years under a wind farm built on Meadow Mountain, about a half mile from his home in rural Meyerdale, Pa.

Larivee said he had a professional engineer measure the noise, and found the windmills showed an average reading of 75 decibels - about the level of noise from a washing machine.

The industry says the average windmill gives off only 45 decibels, but Larivee said the mountainous topography around his home amplifies the volume - and it didn't help that developers clear-cut the trees on the top of Meadow Mountain to make way for the wind.

"It's a low frequency, a rumbling like you are listening to a bass drum," he said. "It's a constant background of 'whoosh, whoosh, whoosh.'" He said he and his family haven't adjusted to the sound. "If you've ever had a leaky faucet, you know it doesn't make a lot of noise, but it drives you nuts."

Larivee, who stresses he's an environmental chemist, said he favored the windmill farm as the green way to go when the facility was built.

But he's now concluded that windmills aren't a very efficient way of generating electricity. The wind farm scrambled his TV and

radio reception, and the turbine blades have claimed the lives of countless bats that used to keep control over the population of mosquitoes and other summer insects.

Carivee's advice to residents of other rural areas planned for wind farms: "Fight it."

Wind Turbine Syndrome

Testimony before the New York State Legislature Energy Committee

March 7, 2006

Nina Pierpont, MD, PhD

MD, The Johns Hopkins University School of Medicine, 1991
 PhD, Population Biology, Princeton University, 1985
 BA, Biology, Yale University, 1977
 Fellow of the American Academy of Pediatrics
www.ninapierpont.com

I am here to talk to you today as a physician-scientist about a clinical phenomenon called Wind Turbine Syndrome. This is relevant to today's hearing because it critically affects implementation of the RPS (Renewable Portfolio Standard) in terms of the siting of industrial wind turbines. Current siting practices (which are solely industry-driven) disregard public health. The supervision of the legislature—of this committee—is needed to create siting standards to protect the citizenry, all the citizenry, including citizens who are rural, old, ill, impaired, and very young.

Federal agencies are trying to put the brakes on willy-nilly wind turbine construction, citing, for instance, wildlife issues. The GAO (Government Accountability Office) last fall told US Fish and Wildlife to get involved. The National Academy of Sciences in April 2005 initiated a 20-month study on environmental impacts whose final report is due in December this year. There also needs to be a focus on human health, and the state needs to step up to the plate in terms of regulation.

I live in Franklin County, the poorest in NY State. Two years ago, after passage of the RPS, wind energy companies showed up there in force, as they have in all the poor, rural parts of the state. They showed up with no controls whatsoever, unregulated by either the legislature or NYSERDA (New York State Energy Research & Development Authority). Our town boards, made up of farmers, teachers, corrections officers, etc., were told, "You guys handle this," by our state representatives. I got involved as a responsible citizen and physician. Over the last 1½ years I have done a lot of reading, research, and interviews. I have spoken at town board meetings and before the St. Lawrence County Legislature, and published alone or with my husband (a retired university professor) numerous editorials and letters to the editor in local newspapers. My focus has been health issues and to some degree wildlife, in which I also have credentials in my PhD.

I get a lot of slander and abuse from the wind salesmen. Their favorites are saying that my abundantly referenced and footnoted articles, like the one before you (note: a separate handout), have "no evidence," or that I think wind turbines cause mad cow disease. The latter smear came from a town meeting in Ellenburg, NY, in October 2004, when I presented information culled from the medical literature on possible effects of low frequency noise. This included a paper out of the UK linking low frequency sound to prion diseases by a complex and highly speculative mechanism. I was very clear how speculative it was, but apparently the concept of something being speculative was over their heads, including over the heads of wind salesmen in the room.

I am not for or against the RPS. I'm an intelligent person and I support renewable energy. I am not here to shoot down wind energy, which probably has its place, though that place is not near people's homes or near schools, hospitals, or other locations where people have to sleep or learn.

I would like to stress that these are not "farms." One doesn't "farm" wind any more than one "farms" water in a hydroelectric dam or "farms" neutrons in an atomic plant. These are large, industrial installations. They make large-scale, industrial noise. "Jet engines" is the most common description I hear in surveying people—a jet engine that doesn't go away and which you can't get used to.

A syndrome in medicine is a constellation of symptoms and findings which is consistent from person to person. Defining a syndrome is the first step in investigating any new disease. The symptom cluster has to make sense in terms of pathophysiology—there has to be a plausible mechanism in terms of how the body and brain work. Defining a syndrome, and making that knowledge available to the medical community, lets other doctors go from scratching their heads over weird presentations of illness which are coming through their offices, to being able to validate and name what is going on and start to do something about it. It also opens the door to epidemiologic studies to define prevalence and risk factors, which will guide prevention and treatment.

Describing and documenting symptoms is the province of physicians. So is research on the causes of diseases. Deciding whether people have significant symptoms is not within the expertise of engineers or specialists in acoustics, even when the symptoms appear to be caused by noise. We physicians appreciate the noise data which engineers provide, but this data has nothing to do with whether people have symptoms or not. One British acoustics expert, Dr. Geoff Leventhall, is especially outrageous in this regard, insisting that people "can't" have symptoms because turbines "don't," he says, produce low frequency noise. His fallback, for which he is well paid by the industry, is that people make up their complaints. But he's not trained to distinguish whether people are making up their complaints, or to know about the range of physical, psychiatric, and neurological symptoms people might have. A related point: the hallmark of a good doctor is one who takes symptoms seriously and pursues them until they are understood (and ameliorated). This includes symptoms related to the brain, our most complex organ—symptoms which may be neurologic, psychiatric, or physical.

* Three doctors that I know of are studying the Wind Turbine Syndrome: myself, one in England, and one in Australia. We note the same sets of symptoms. The symptoms start when local turbines go into operation and resolve when the turbines are off or when the person is out of the area. The symptoms include:

- 1) Sleep problems: noise or physical sensations of pulsation or pressure make it hard to go to sleep and cause frequent awakening.
- 2) Headaches which are increased in frequency or severity.
- 3) Dizziness, unsteadiness, and nausea.
- 4) Exhaustion, anxiety, anger, irritability, and depression.
- 5) Problems with concentration and learning.
- 6) Tinnitus (ringing in the ears).

Not everyone near turbines has these symptoms. This does not mean people are making them up; it means there are differences among people in susceptibility. These differences are known as risk factors. Defining risk factors and the proportion of people who get symptoms is the role of epidemiologic studies. These studies are under way.

Chronic sleep disturbance is the most common symptom. Exhaustion, mood problems, and problems with concentration and learning are natural outcomes of poor sleep.

Sensitivity to low frequency vibration is a risk factor. Contrary to assertions of the wind industry, some people feel disturbing amounts of vibration or pulsation from wind turbines, and can count in their bodies, especially their chests, the beats of the blades passing the towers, even when they can't hear or see them. Sensitivity to low frequency vibration in the body or ears is highly variable in people, and hence poorly understood and the subject of much debate.

Another risk factor is a preexisting migraine disorder. Migraine is not just a bad headache; it's a complex neurologic phenomenon which affects the visual, hearing, and balance systems, and can even affect motor control and consciousness itself. Many people with migraine disorder have increased sensitivity to noise and to motion—they get carsick as youngsters, and seasick, and very sick on carnival rides. Migraine-associated vertigo (which is the spinning type of dizziness, often with nausea) is a described medical entity. Migraine occurs in 12% of Americans. It is a common, familial, inherited condition.

To keep our balance and feel steady in space, we use three types of input: from our eyes (seeing where we are in space), from stretch receptors in joints and muscles, and from balance organs in the inner ear. At least two of these systems have to be working, and agreeing, to maintain balance. If the systems don't agree, as in seasickness or vertigo, one feels both ill and unsteady. Wind turbines impinge on this system in two ways: by the visual disturbance of the moving blades and shadows, and by noise or vibration impacting the inner ear.

Other candidate risk factors for susceptibility to Wind Turbine Syndrome are age-related changes in the inner ear. Five percent (5%) of otherwise healthy people from age 57 to 91 experience dizziness, and 24% experience tinnitus or ringing. Damage to the ears or hearing from other causes, such as noise exposure, is also a potential risk factor.

Inner ear organs are closely linked, by proven neurological connections, to the brain systems which control mood, anxiety, and one's sense of well-being. Disturbing the inner ear disturbs mood, not because a person is a whiner or doesn't like turbines, but because of neurology.

Data from a number of studies and individual cases document that in rolling terrain, disturbing symptoms of the Wind Turbine Syndrome occur up to 1.2 miles from the closest turbine. In long Appalachian valleys, with turbines on ridge-tops, disturbing symptoms occur up to 1.5 miles away. In New Zealand, which is more mountainous, disturbing symptoms occur up to 1.9 miles away.

In New York State, with its mixed terrain, I recommend a setback of 1.5 miles (8000 ft.) between all industrial wind turbines and people's homes or schools, hospitals, or similar institutions. This setback should be imposed immediately for turbines not yet built.

The legislature might want to set up a panel of clinicians to review the data and medical information I refer to here, but until this happens, and as research continues, a moratorium on all wind turbine construction within 1.5 miles of homes would be appropriate.

To recapitulate, there is in fact a consistent cluster of symptoms, the Wind Turbine Syndrome, which occurs in a significant number of people in the vicinity of industrial wind turbines. There are specific risks factors for this syndrome, and people with these risk factors include a substantial portion of the population. A setback of 1.5 miles from homes, schools, hospitals, and similar institutions will probably be adequate, in most NY State terrain, to protect people from the adverse health effects of industrial wind turbines.

Health Effects of Wind Turbine Noise

Nina Pierpont, MD, PhD
www.ninapierpont.com

February 4, 2006

Industrial wind turbines produce significant amounts of audible and low-frequency noise. Dr. Oguz A. Soysal, Professor and Chairman of the Dept. of Physics and Engineering at Frostburg State University in Maryland, measured sound levels over half a mile away from the Meyersdale, PA, 20-turbine wind farm. Typical audible (A-weighted) dB (decibel) levels were in the 50-60 range, and audible plus low-frequency (C-weighted) dB were in the 65-70 range.¹ 65-70 dB is the loudness of a washing machine, vacuum cleaner, or hair dryer.² A difference of 10 dB between A and C weighting represents a significant amount of low-frequency sound by World Health Organization standards.³

The noise produced by wind turbines has a thumping, pulsing character, especially at night, when it is more audible. The noise is louder at night because of the contrast between the still, cool air at ground level and the steady stream of wind at the level of the turbine hubs.⁴ This nighttime noise travels a long distance. It has been documented to be disturbing to residents 1.2 miles away from wind turbines in regular rolling terrain,⁵ and 1.5 miles away in Appalachian valleys.⁶

At night, the WHO recommends, the level of continuous noise at the outside a dwelling should be 45 dB or less, and inside, 30 dB or less. These thresholds should be even lower if there is a significant low-frequency component to the sound, they add – as there is for wind turbines. Higher levels of noise disturb sleep and produce a host of effects on health, well-being, and productivity.⁷

The decibel is logarithmic. Increasing the dB level by 10 multiplies the noise level by 10. Increasing the dB level by 20 multiplies the noise level by 100 (and 30 dB multiplies by 1000, etc.). Thus the 65 dB measured day and night half a mile from the Meyersdale wind farm is 100 times louder than the loudest continuous outdoor nighttime noise (45 dB) recommended by the WHO.

Typical ordinances proposed or passed for NY State communities considering industrial wind turbines allow A-weighted noise levels of 50 dB and construction of turbines only 1000 ft. from dwellings. These ordinances meet neither WHO nor NYS DEC standards, especially compared to the very low ambient noise levels (with dB levels typically in the 20's) in rural NY.⁸

The health effects of excessive community noise are carefully documented in the WHO report with reference to scientific and medical literature. Effects relevant to wind turbines, in terms of dB levels and noise type, are paraphrased and summarized from this report.

- For people to understand each other easily when talking, environmental noise levels should be 35 dB or less. For vulnerable groups (hearing impaired, elderly, children in the process of reading and language acquisition, and foreign language speakers) even lower background levels are needed. When noise interferes with speech comprehension, problems with concentration, fatigue, uncertainty and lack of

self-confidence, irritation, misunderstandings, decreased work capacity, problems in human relations, and a number of stress reactions arise.⁹

- Wind turbine noise, as described above and experienced by many turbine neighbors, is easily within the decibel levels to disturb sleep. Effects of noise-induced sleep disturbance include fatigue, depressed mood or well-being, decreased performance, and increased use of sedatives or sleeping pills. Measured physiologic effects of noise during sleep are increased blood pressure and heart rate, changes in breathing pattern, and cardiac arrhythmias.¹⁰ Certain types of nighttime noise are especially bothersome, the authors note, including those which combine noise with vibration, those with low-frequency components, and sources in environments with low background noise.¹¹ All three of these special considerations apply to industrial wind turbines in rural NY State. Children, the elderly, and people with preexisting illnesses, especially depression, are especially vulnerable to sleep disturbance.
- Noise has an adverse effect on performance over and above its effects on speech comprehension. The most strongly affected cognitive areas are reading, attention, problem solving, and memory. Children in school are adversely affected by noise, and it is the uncontrollability of noise, rather than its intensity, which is most critical. The effort to tune out the noise comes at the price of increased levels of stress hormones and elevation of resting blood pressure. The adverse effects are larger in children with lower school achievement.¹²
- What is commonly referred to as noise "annoyance" is in fact a range of negative emotions, documented in people exposed to community noise, including anger, disappointment, dissatisfaction, withdrawal, helplessness, depression, anxiety, distraction, agitation, and exhaustion.¹³ Numerous reports from neighbors of new industrial wind turbine installations document these symptoms. The percentage of highly annoyed people in a population starts to increase at 42 dB, and the percentage of moderately annoyed at 37 dB.¹⁴

Low-frequency sound is also sensed as pressure in the ears. It modulates the loudness of regular audible frequencies, and is sensed as a feeling, or vibration in the chest and throat.¹⁵ Neighbors of industrial wind turbines describe the distressing sensation of having to breathe in sync with the rhythmic thumps of the turbine blades, especially at night when trying to sleep.

The participants in noise studies are selected from the general population and are usually adults. Vulnerable groups of people are underrepresented. Vulnerable groups include:

- People with decreased personal abilities (old, ill, or depressed people)
- People with particular diseases or medical problems
- People (such as children) dealing with complex cognitive tasks, such as reading acquisition
- People who are blind or who have hearing impairment
- Fetuses, babies and young children
- The elderly

These people may be less able to cope with the impacts of noise exposure and at greater risk for harmful effects than is documented in studies. Attention needs to be paid to them when developing regulations and setback requirements for industrial wind turbines and other sources of annoying and debilitating noise.

Wind turbines also create moving visual disturbances, especially early and late in the day when the long shadows of moving blades sweep rhythmically over the landscape. That portion of the population which is susceptible to vertigo, unsteadiness, or motion sickness (including many children and a large proportion of the elderly) will be vulnerable to unsteadiness and nausea when subjected to this visual disturbance. People with seizure disorders are susceptible to triggering of seizures by the strobe effect of seeing the sun through the moving blades.

Wind Farm Resistance

What's All the Fuss About? Part I

Staff Reports

A meeting was recently held at a camp on Lake Titus, which is situated on the eastside of Route 30 ten miles south of Malone in Franklin County at the northern reaches of the Adirondacks. Any traveler will see the yellow and black STOP WIND TURBINES signs along the roadway to Malone.

Lake property owners gathered to hear a presentation by Professor Calvin Luther Martin, retired history professor from Rutgers University, warning of the perils of huge wind turbines which have been proposed for construction on the westerly viewscape of those present. Professor Martin and his wife, Nina Pierpont Martin, a pediatrician, are local wind turbine activists.

Professor Martin first presented a compelling video tape featuring persons living in the near vicinity of wind turbine farms. These farms have as many as 50 or more turbines each standing 400 plus feet tall their blades and motors making incessant noise, creating a strobe effect which has caused neurological side effects while destroying the viewscape of everyone who lives nearby.

Locally wind turbines have been proposed for the Tug Hill Plateau northwest of Utica. The Utica Phoenix presents this material to serve as a learning tool for area residents.

According to Professor Martin the North Country is being transformed into a huge industrial wind turbine gulag. (visit www.nyiso.com and check out the NYISO Interconnection Queue)

This is unless the many hundreds of people who oppose them can put a stop to this folly. There are now five anti-windfarm groups in Clinton & Frank-

lin counties. An available videotape will describe what residents in Meyersdale, PA, and Wethersfield, NY, are saying about these developments. The inhabitants of these localities are forbidden from negative comment because of a "gag" clause they sign with the wind companies to whom they have leased their land or signed an easement agreement. The wind

companies assert property values are not damaged. This is false. Wind companies pull off this lie by resorting to a con game right out of the Wild West. The wind companies buy, at full market value, the homes of people who threaten to sue them for destroying the value of their homes. This is often because of the low frequency thump from the turbines, for days and weeks on end. Then the wind guys re-sell these homes at whatever the market

Continued on page 6

continued from page 1

offers, which is anywhere from 20% to 80% below market value. By this sleight-of-hand, wind companies can announce that "property values are not degraded."

A few other points are worth noting. The wind companies are owned by JP Morgan Chase - Noble Environmental, Goldman Sachs - Zilkha, now Horizon, PPM - a Scottish firm owning Atlantic Renewable, etc. This translates into billions in tax write-offs and millions more in tax subsidies, from your tax dollars, to large corporations—while your electric bills go up. Notice your Systems Benefit Charge on your next power bill. Your bill has gone up already.

These wind companies sell their electricity to NEMO and NYSEG, who then charge you more for your electricity, since the higher cost of wind electricity is passed on to you. Turbines work only 25% of the time, meaning that for 75% of their 25-year projected lifespan they sit idle, "harvesting" nothing but your tax dollars and yes, the state allows this.

Thousands of giant turbines chum away across America and yet, all together, over the next 25 years, these thousands of turbines will generate enough juice to keep this country pow-

ered for ... just 19 days. Imagine gerbils on a treadmill: wind turbines and gerbils generate power according to roughly the same inefficiencies.

In case you're thinking wind turbines will get us off foreign oil, you're dead wrong. They have no impact on foreign oil imports. Foreign oil goes into your gas tank and basement furnace. Think about it. Does your car run on electricity? Do you heat your home with electricity?

Here are some simple facts. The automobile is responsible for nearly 70% of America's oil consumption. There's where all that foreign oil is going! Industry accounts for about 24%, home heating oil accounts for another roughly 4%, and about 2% , easily covered by our domestic oil production, is used to produce electricity.

Fact is, virtually all our electricity is produced by coal, natural gas, hydro, or nuclear power plants—not by burning oil. Coal-fired plants are having their nitrogen, sulfur, mercury, and even carbon emissions cleaned up as we speak, though the process is erratic and maddeningly slow because Washington drags its feet.

Perhaps more to the point, wind energy is everywhere added to existing

continued on page 17

influence, and support a successful, young, African American student.

continued from page 6

forms of electricity production rather than replacing anything currently operating. Such is the experience worldwide. Hence, to argue wind turbines will replace coal-burning plants is ill-informed.

Remember, electricity is not stored anywhere in the grid. Hence coal-fired plants are kept in spinning reserve to make up for those 19 years out of 25 when wind turbines simply are not working. Either because the wind isn't blowing or the turbines are broken down, which is common.

Since wind energy cannot be produced "on demand" conventional "on demand" sources must be kept in spinning reserve, ramping up and down to compensate for erratic wind-produced energy. And, yes, power brown-outs are the order of the day. Witness several in Spain, which is heavily wind-turbined, this past winter, and witness grid operators in Denmark and Germany, also heavily wind-farmed, frantically trying to ward these off with varying degrees of success.

Wind Farm Resistance Why All the Fuss? Part II

The Phoenix gives special recognition to Calvin Luther Martin, PhD, Associate Professor of History (ret.) Rutgers University, NJ and his wife Nina Pierpont, MD, PhD Clinical Professor of Pediatrics (2000-03) College of Physicians & Surgeons Columbia University for their contribution to this series.

Each individual wind turbine includes a 60 ton nacelle on top (as big as Greyhound bus), 26 stories up, housing a huge gearbox & generator. Also, not to be missed is 200 gallons of oil in the nacelle. A question might be posed, whose fire department puts out the fire when lightning strikes or the gearbox/generator overheats—26 stories high? These monstrosities are huge lightning rods. There is evidence some of the turbines dump current into the ground to get rid of excess, presumably when it's not needed on the grid. This is vehemently denied by the wind salesmen, but dairy farmer Scott Straka in Lincoln Township, Wisconsin, and his electrician and I disagree. The ground is a good conductor.

They also include a colossal 40 ton propeller, with wingspan equal to Jumbo Jet's. This propeller is started by running the generator backwards, thus drawing non-metered power off the grid—see the Searsburg, Vt., audit for this, which causes a roar neighbors liken to a jet engine.

When wind speeds exceed 60 mph, the propeller is stopped by a brake which has been known to produce a loud scream.

Either a 30x30x30 or 30x30x10 concrete footer is required to be poured into the ground, sometimes down to bedrock. Questions arise as to the effects upon subsoil water

movement and nearby wells, and sound transmission and vibration? A recent study out of Keele University, UK, shows significant ground vibration, despite Noble Environmental salesmen arguing otherwise. "Microseismic and infrasound monitoring of low frequency noise & vibrations from windfarms," by Prof. Peter Styles et al., July 2005, refutes Noble's claim. The significance of this ground vibration is probably more meaningful to people and livestock and wildlife with hearing and balance hypersensitivity, as in the inner ear of humans. Again, the vibration effects on wildlife & livestock are totally unknown.

It is estimated by biologists, Bat Conservation International, Austin, Texas, and Professor Jessica Kerns, Univ. of Maryland, investigating bat deaths at the Mountaineer (W. Va.) and Meyersdale (Pa.) windfarms, both owned by Florida Power & Light, that each turbine at each site kills many hundreds of bats per year. Some turbines kill up to 4,000 bats per year. Why this is so is a mystery. Curiously, bats are attracted to the spinning blades, with a tip speed of 200 mph, only when the generator is turned on, not when the propeller is merely spinning. Bat mortality has been so appalling at these two sites that Florida Power and Light has forbidden all further research.

Add to bat deaths, bird deaths and wild animal deaths from habitat destruction. Each turbine occupies several acres of land, not to mention access roads and power lines to the grid which encroach on natural habitat.

The matter of low frequency noise is also troubling in terms of wildlife health & behavior, live-

Continued on page 5

stock health & behavior, and, of course, human health especially inner ear problems from low frequency noise. The wind salesmen deny virtually all of this, but the evidence is mounting and it is alarming.

The National Academy of Sciences recently appointed a blue ribbon panel of scientists to spend the next 20 months investigating the hazards of wind turbines. This is, of course, tacit acknowledgement that there are problems the wind energy industry has papered over. This 20-month study period should be interpreted by the rest of us as a signal to put all windfarm development on hold. Yet there is no moratorium in place in NYS. Some opponents say our state government is irresponsible for not enacting one.

Many people around the world, including NYS, who find themselves neighbors of wind turbines will tell you there is often a very distressing thumping sound coming from the blades. It is a pressure wave created by the blade passing the turbine tower, although the physics of this is complex. The sound is loud. Neighbors compare it to a shoe in a tumble dryer, or an "endless train". The sound travels for miles, depending on topography, readily penetrates houses, has a significant low frequency component, which seems to foul up inner ear function, triggering the dizziness, nausea, sleeplessness, ringing in the ears, and anxiety frequently described by neighbors. The sound is definitely worse at night owing to nighttime temperature inversions, the calm at ground-level coupled with the wind at the turbine hub. Hence there is no ambient noise at ground-level to mask turbine thump.

A study was done by Nina Pierpont, MD, PhD, analyzing hundreds of reports of turbine noise and linking neighbors' complaints with inner ear and other neurological problems. Pierpont recommends a 1.5 mile figure setback from residential property. Pierpont's 1.5 mile setback is corroborated by Dick Bowdler, President of New Acoustics, a Scottish firm that has been studying turbine noise for years. Bowdler works for both wind energy companies and windfarm neighbors and calls for a 1.25 mile setback. Like Pierpont, Bowdler says the wind salesmen's proposed turbine noise level of 55 dB(A) is, in his words, "outrageous" Log onto <http://www.newacoustics.co.uk> for more information.

we're here today. msnbc.com

Points to Remember: 1. wind turbines industrialize and degrade our rural landscape 2. wind farms have no impact on foreign oil imports 3. what they "farm" is not wind so much as tax write-offs for JP Morgan and Goldman Sachs and tax subsidies for the wind salesman 4. wind turbines are a tremendous hazard to bats and birds in fly zones 5. the turbines demonstrably trash adjoining property values by 20-80%. 5. turbine noise drives neighbors to their doctors for sleeping pills and anti-depressants (witness Meyersdale, Wethersfield, Fenner, Backbone Mtn., Lincoln Township, etc.) 6. wind turbines chop and reflect microwave transmission, fragmenting cell phone and TV reception as well as emergency communications (see Leonard J. Koehnen, PE, Consulting Engineer, "Wind farms and their effects on public safety radio systems," Feb. 2005, St. Paul, MN, lenk911@onvoymail.com). 7. the wind companies routinely, now, back out of their PILOT and tax promises to school boards and municipalities (witness several court cases started recently in PA).

Even on the calmest nights, the endless drumming goes on; windows closed, pillows over the head, it is still inescapable. While we were led to believe this would be a clean, quiet, pristine, and environmentally friendly way to address energy problems and give a huge boost to our ailing economy, I feel we have been tricked. There appears to be no recourse or plan to compensate us for property value losses, erosion of our quality of life, or mental anguish. Besides these 44 wind turbines, thousands more are in the pipeline! God help!

To the Editor
The Caledonian Record

To Whom This May Concern

As producer and director of the documentary Life Under a Windplant, a video shown widely in your area, I'd like to respond to the spurious claims about it ~~wrought~~ by your not-so-very local wind developer. But first, you should know I'm a retired university administrator who has no financial interest one way or another over this wind issue, nor do I nor any members of my family own property in the viewshed of any proposed windplant. On the other hand, wind developers hope to make a financial killing, and, despite their penchant for labeling opponents as NIMBYs, themselves live hundreds of miles from their project. The industry is in fact a spiritual descendant of Enron, the "energy" company that, before its demise, owned and operated the nation's largest collection of wind facilities; it pioneered the tax shelter as a commodity. After several years of researching the wind industry, I've concluded the relatively feeble energy it produces is a front for the real business of generating Enronesque tax avoidance schemes benefiting a few at the expense of many, while playing havoc with the environment (while claiming to be saving it). It's an environmental hoax and an economic sham. More than 2500- 400 foot 1.5 MW turbines, spread over many hundreds of miles of forested ridgetops, would not displace one 1600MW coalplant. The wind industry, as it targets huge powerplants along the uplands of our region, is a placebo solution to the problems wrought by our dependence on fossil fuels, distracting from the necessary level of discourse-- and political action-- for achieving genuinely functional responses

About the video.

The prices Somerset Wind in Pennsylvania paid for the properties near its windplant were comparable to prices paid for similar properties in the area and in line with the price previous buyers had paid. Although the properties in the video were assessed for tax purposes at around \$20,000 (as of 1997), they initially had sold for fair market value at \$80,000 and \$74,000 respectively --in 1998 and 1997. As every realtor and appraiser knows, assessed tax value lags considerably behind market value, often by as much as 500 percent. The property owners who precipitated the sale did so because of windplant-caused nuisances. In 2002, Somerset Wind bought these properties for \$104,540 and \$101,049 respectively—and within six months, sold them for \$65,000 and \$20,000 respectively—the first to a windplant employee and the second to an existing wind lessor. The quotes of the prices listed in the documentary are those listed in the deeds. The deeds are public records. And the reason the developer bought the properties in the first place was to forestall a lawsuit brought on because of the very real nuisances that the windplant created--nuisances actually named in an exculpatory easement in the new deeds. You wind developer's chutzpa here is simply amazing....

Moreover, the claim that the windplant noise in the documentary was somehow rigged is a damnable lie. If anything, the actual sound was muted in the documentary. Note that the video several times indicates how far the recorded noise was from the wind turbines. Because we anticipated what the wind flaks would say about dubbing, we recorded the voice you hear over the sound, showing that one had to practically shout to be heard nearly a half mile from the windplant. You might also ask any of the Meyersdale participants in the documentary whether they think the sound was dubbed over or modified in any way. Or ask whether the wind developer puts language in his leases holding his company harmless from a variety of nuisances, including noise--as is the case in Berlin, Pennsylvania.

Wind noise is generally much less in the summer and early fall than at other times of the year in

part because the wind at these seasons often has a desultory quality, typically blowing with much less intensity. Higher frequency turbine-induced sound along valley ridges is often a hit or miss affair—some get assaulted by it while others hear nothing. We recorded the noise in January. However, it is the low frequency noise that is the real culprit. This is expensive to document. But nonetheless very real. This is what Rodger Hutzell in Meyersdale experiences. Finally, ask your wind developer whether he or his staff are going to attend the "First International Conference on Wind Turbine Noise" in Berlin, Germany this October 17-18—advertised with the banner headline, "Wind Turbine Noise: Perspectives for Control."

The 340 foot tall turbines near Berlin, Pennsylvania are four years old and I can't vouch for how they're maintained. But I can vouch for their horrific noise. Ten miles down the road at Meyersdale, the "newer" 376 foot Danish Micon turbines make as much noise and, according to Meyersdale Wind's fact sheet, these are indeed maintained by two employees. Similarly, a "new" windplant in nearby Thomas, West Virginia, also causes significant noise, and it, too, has maintenance employees.

In *Life Under a Windplant*, I wanted to feature the human side of the problem with industrial wind, letting the people and the images tell the story. It is the old story of colonialism, with distant capital exploiting the people and resources of the hinterlands to give the illusion of progress. At the same time I wanted to show the falsity of several of the many outrageous claims the wind industry continues to make in pursuit of profit. No negative consequences seem to attach to the industry for making a cascade of promises that unlikely will be fulfilled, such as providing significant new jobs and local revenues while contributing to US energy independence, such as improving air quality by reducing current levels of fossil fuel combustion; such as causing no nuisances and actually enhancing nearby property values. What, for example, would the penalty be in Vermont if the wind developer's promises about the amount of local taxes a community would receive failed to materialize because of an arcane legal tax offset known only to skilled accountants? Or, would scores of thousands of homes really be "powered" by an energy source that at best functions less than 30 percent of the time?

For those who would like to know more about these issues, please visit the website I helped create: www.stopillwind.org. Or go to the the Maryland Public Service Commission website, type in Case No. 9108, and read my 40-page direct testimony, with many documenting attachments, which I submitted as an intervenor in a Maryland windplant application. Above all, please remember that if something seems too good to be true, it almost always is.

Sincerely,

Jon Boone

Remarks Of Senator Alexander - Windmill Legislation Introduction

May 13, 2005 by Senator Lamar Alexander (R-TN)

Summary:

Sen. Lamar Alexander (R-TN) -- I am here today to introduce - along with the senior senator from Virginia, Senator John Warner - the Environmentally Responsible Wind Power Act of 2005.

I am here today to introduce - along with the senior senator from Virginia, Senator John Warner - the Environmentally Responsible Wind Power Act of 2005.

Our legislation provides for local authorities to be notified and have a role in the approval of the siting of tens of thousands of massive wind turbines that will be built in America under current policies. It also ensures that the federal government does not subsidize the building of these windmills - which are usually taller than a football field is long - within 20 miles of a military base or a highly scenic location, such as a national park or offshore.

Senator Warner and I introduce our legislation today because next week the Senate Energy Committee is scheduled to begin markup of one of the most important pieces of legislation of this session, an energy bill. The Energy Committee's work -combined with the work of the Environment and Public Works Committee and the Finance Committee - should this year produce a clean energy bill that will, over time, lower prices of natural gas and oil and reduce our dependence on overseas oil.

This will be legislation for American blue collar workers, for farmers and for homeowners. It is urgently needed. Natural gas prices are the highest in the industrialized world. Gasoline prices are at record levels. We cannot keep our jobs and our standard of living if we do not put in place policies that will provide our country with new steps toward conservation and an adequate supply of low cost, reliable, clean, American-produced energy. Senator Warner and I both intend to be in the middle of this discussion. He is a senior member of the Environment and Public Works Committee, I am chairman of the Energy Subcommittee.

I am grateful for and am greatly encouraged by the leadership of the Energy Committee Chairman, Senator Domenici, and the ranking Democrat, Senator Bingaman, and the committee staffs, who have worked especially hard to create a framework for a more aggressive, bipartisan piece of legislation.

One part of our energy debate will be about wind power, which is the subject of our legislation today. This is because several of our colleagues have proposed something called a Renewable Portfolio Standard, or RPS, which would require power companies to produce 10 percent of all their electricity from renewable sources by 2025. These renewable sources are wind, hydro, solar, geothermal and biomass. Today these

renewable sources produce about 9 percent of U.S. electricity needs. This RPS is not to be confused with a Renewable Fuel Standard - which is a requirement that gasoline contain a certain percentage of ethanol. A Renewable Fuel Standard is entirely different from a Renewable Portfolio Standard and may well be part of the final legislation.

It is important for our colleagues to know that a Renewable Portfolio Standard or RPS is all about wind. There are very few opportunities to build new dams and expand hydro power, which produces 7 of the 9 percent of renewable power we use today. Of the remaining 2 percent of renewal power sources, current subsidies aren't enough to increase solar power by very much. More research and development is needed to make biomass more efficient. And there is limited availability of geothermal power, that is, drawing power from water that is heated underground.

Which leaves wind power. Experts agree that the bottom line is that a requirement that electric companies produce 10 percent of their electricity from

Which leaves wind power. Experts agree that the bottom line is that a requirement that electric companies produce 10 percent of their electricity from renewable energy, if it could be achieved at all, would mean that about 70 percent of the increase would come from wind. In other words, we would go from producing about 1 percent of our electricity from wind to 7 or 8 percent.

Testimony before our Energy Committee and most other sources suggest that to produce this much wind energy in the United States could require building more than 100,000 of new, massive wind turbines. We have less than 7,000 such windmills in the U.S. today, with the largest number in Texas and California.

Testimony also indicated that, even without the RPS, if Congress continues its sustained generous subsidy for wind production for the next 10 years, it will guarantee that the U.S. has about 100,000 of these windmills by 2025. According to the Treasury Department, this wind subsidy, if renewed each year for the next five years, would reimburse wind investors for 25 percent of the cost of wind production and cost taxpayers \$3.7 billion over those 5 years. General Electric Wind, one of the largest manufacturers of wind turbines, has experienced a 500 percent growth in its wind business this year due to the renewal of the wind production tax credit last year.

I want to make sure that my colleagues know that there are serious questions about how much relying on wind power will raise the cost of electricity, questions about whether there are better ways to spend \$3.7 billion in support of clean energy, questions about whether wind even produces the amount of energy that is claimed. My studies suggest that at a time when American needs large amounts of low-cost reliable power, wind produces puny amounts of high-cost unreliable power. We need lower prices; wind power raises prices. We will have an opportunity in our debates and further hearings to examine these questions.

But the legislation we offer today is about a different question: the siting of 100,000 of these massive machines.

The idea of windmills conjures up pleasant images - of Holland and tulips, of rural America with windmill blades slowly turning, pumping water at the farm well. My grandparents had such a windmill at their well pump. That was back before rural electrification.

But the windmills we are talking about today are not your grandmother's windmills.

Each one is typically 100 yards tall, two stories taller than the Statue of Liberty, taller than a football field is long.

These windmills are wider than a 747 jumbo jet.

Their rotor blades turn at 100 miles per hour.

These towers and their flashing red lights can be seen from more than 25 miles away.

Their noise can be heard from up to a half mile away. It is a thumping and swishing

Read

Sen alex

Read if time allows

* sound. It has been described by residents that are unhappy with the noise as sounding like a brick wrapped in a towel tumbling in a clothes drier on a perpetual basis.

* These windmills produce very little power since they only operate when the wind blows enough or doesn't blow too much, so they are usually placed in large wind farms covering huge amounts of land.

As an example, if the Congress ordered electric companies to build 10 percent of their power from renewable energy - which as we have said, has to be mostly wind - and if we renew the current subsidy each year, by the year 2025, my state of Tennessee would have at least 1,700 windmills, which would cover land almost equal to two times the size of the city of Knoxville.

If Virginia were to produce 10 percent of its power from wind and the subsidies continue, it would probably need more than 1,700 windmills. These windmills would take up enough land to equal the land mass of three cities the size of Richmond, Virginia.

In North Carolina, to supply 10 percent of electricity from wind if the subsidies continue, it would take up the landmass of the Research Triangle - the Raleigh, Durham, Chapel Hill area.

According to testimony before our committee, in Tennessee and Virginia, these windmills would work best and perhaps only work at all along ridge tops.

So, if present policies are continued, we could expect to see in hundreds of football field sized towers with flashing red lights atop the blue ridges of Virginia, above the Shenandoah Valley, along the foothills of the Great Smoky Mountains, on top of Signal Mountain, and on top of Lookout Mountain and Roan Mountain in Tennessee and down the Tennessee River Gorge, which the city of Chattanooga has just spent 25 years protecting and now calls itself the scenic city.

I hope that we decide, Mr. President, that there are better ways to provide clean energy than to spend \$3.7 billion of taxpayer dollars over the next 5 years on windmills. I hope we decide that we need a real national energy policy - instead of a national windmill policy.

I hope we decide that there are better and cheaper ways to discuss carbon.

At least there are some important questions to answer.

* What will this do to our tourism industry? Will 10 million visitors a year who come to enjoy the Great Smokies really want to come see ridge tops decorated with flashing red lights and 100-yard tall windmills?

* What happens to electric rates when the federal subsidy disappears?

Who will take down these massive structures if we decide we don't like them or if they don't work?

Who is making the money on all this?

Read

Why are some of European countries who pioneered wind farms now slowing down or even stopping their construction in some places?

Clearly there are more sensible ways to provide clean energy than spending \$3.7 billion of taxpayers' money to destroy the American landscape.

\$3.7 billion would provide us enough money to give 185,000 Americans a \$2,000 subsidy to buy a hybrid or clean diesel vehicle - which would about double the number of hybrid cars expected to be sold in the U.S. during 2005. Hybrid cars burn about 60 percent of the amount of gasoline than conventional cars burn.

\$3.7 billion would provide enough money for loan guarantees to help launch a dozen new clean coal gasification plants and help transform the marketplace with a new technology for clean, American produced energy that would lower natural gas prices and reduce our dependence on foreign oil.

For 3.7 billion we could provide loan guarantees for at least a half dozen new technology nuclear power plants and have a billion dollars left over for research and development on the recapture of carbon that might be produced by coal plants or to encourage conservation practices.

Just by way of comparison, a nuclear power plant such as TVA's Sequoyah nuclear plant would produce about the same amount of energy as the windmills which a RPS and tax subsidy would build in Tennessee - and the electricity would be available even when the wind wasn't blowing.

While we are debating the wisdom of wind policies, these massive turbines are being built across America, 6,700 of them so far, 29 of them in Tennessee. The Tennessee Valley Authority recently announced it had signed a 20-year contract with a group of investors from Chicago to build 18 huge windmills atop a 3,300 foot ridge on Buffalo Mountain in East Tennessee.

So the purpose of our legislation is to give citizens the opportunity to have some say in where these massive structures are located in their communities and to make sure that the Congress does not subsidize the destruction of the American landscape near our national parks or other highly scenic areas or build such tall structures dangerously close to our military bases.

First, the bill ensures that local authorities are notified and have a role in the approval of new windmills to be built in their areas of jurisdiction. This means that at the same time a proposed windmill is filed with the Federal Energy Regulatory Commission, FERC would notify the local authority with zoning jurisdiction.

Within 120 days, under our bill, local authorities may support or oppose the project. If they support it, the windmill may qualify for FERC market-based rates (allowed to charge wholesale prices) and may be exempt from a series of regulations that restrict the operations of public utilities. If local authorities oppose the windmill, it may still go forward, but subject to regulations (called PUHCA) and unable to charge wholesale rates or issue a qualified rate schedule. If no action is taken by the local authority, the FERC

process would proceed as though the authority were in support.

I believe it is crucial that local authorities have a chance to consider the impact of such massive new structures before dozens or hundreds of them begin to be built

Continued next pg

I believe it is crucial that local authorities have a chance to consider the impact of such massive new structures before dozens or hundreds of them begin to be built in their communities. In many other instances involving the location of facilities generating power, state and local governments have developed laws giving citizens an opportunity to comment or even stop the location of facilities they don't want. Our legislation gives communities that do not now have such laws the chance to do that. Then this legislation sunsets in 7 years.

Second, our legislation provides protection to highly scenic areas and to military bases. It does so by eliminating tax subsidies for any windmill within 20 miles of a World Heritage Area (which includes many national parks), a military base or offshore.

Under the bill, placement of a windmill within 20 miles of such a site shall also require the completion of an environmental impact statement. Further any windmill that is to be constructed within 20 miles of a neighboring state's border may be vetoed by that neighboring state. In other words, if the neighboring state can see it, and don't want it, they can veto it.

I believe that during our debates we will find there are better ways to produce a low-cost, reliable supply of American energy than by spending \$3.7 billion over the next 5 years requiring power companies to produce energy from giant windmills that raise electric rates, only work when the wind blows, and destroy the American landscape.

The legislation that Senator Johnson and I have introduced, the Natural Gas Price Reduction Act of 2005, includes support for aggressive conservation, new clean coal gas plants, new supplies of domestic natural gas, and, for the time being, easier import of liquefied natural gas.

I believe there is an important place in our energy bill for renewable fuels, such as ethanol. And I believe there is an important place for renewal energy sources. For example, the legislation Senator Johnson and I introduced a few weeks ago would increase from 10 to 30 percent the tax credit for commercial investments in solar technology that generates electricity, heats or cools a structure, uses fiber optics and illuminates a building, or provides solar process heat. It provides a similar 30 percent tax credit for a solar system that heats a home. But it is important to keep in mind that, aside from wind, renewable energy can only provide about 3 percent of America's total energy needs over the next 20 years.

In the United States of America, Mr. President, the wholesale destruction of the American landscape is not an incidental concern. The Great American Outdoors is an essential part of the American character. Italy has its art. Egypt has its pyramids. England has its history. And we have the Great American Outdoors.

While we debate the merits of so much subsidy and reliance on wind power, we should at the same time protect our national parks, our shorelines and other highly scenic areas, and we should give American citizens the opportunity protect their communities and landscapes before it is too late.

Wind-farm law passes

MALONE — The 15 or so people in attendance applauded Wednesday night when the Malone Town Council adopted a local law that severely restricts the construction of wind towers.

May 25, 2006 by Denise A. Raymo, Staff Writer in Press Republican

Language in the unanimously passed law limits tower heights to 85 feet on non-agricultural land and 100 feet for property within an ag district as long as the power generated is used for on-site consumption.

Person after person stood to praise the members for their courage in adopting the measure that takes effect as soon as it is on file with the Secretary of State's Office in Albany.

No wind-energy companies have proposed a project in the Town of Malone, but there are plans under way in several sites in Clinton County and a formal plan could be presented to the Town of Brandon in the coming months from Noble Environmental Power.

During a public hearing prior to the Town Council's regular meeting, several residents spoke in favor of the restrictive policy.

who will conduct them?*

Location Beth Moshier offered appreciation for "your high level of integrity" and "for not selling out." John McCarthy, who is a member of the town's Planning Board, said he was opposed to wind-farm operations because there are no clear benefits to the town or its people, adding that the country's reliance on foreign oil needs to be addressed.

The lone audience member who spoke in favor of future wind projects was Tom Schultz, a Malone artist, who said the Maple Ridge Wind Project he sees in the Lewis County Town of Lowville "is very beautiful" and that the people who live near them have no complaints.

He said the North Country should welcome such new technology.

Others, including Town Supervisor Howard Manely, ~~disagreed.~~ **said**

In fact, he said, it was seeing the first 120 towers of the 198-tower Lowville project that made him change his mind about the wisdom of wind farms in Malone.

"I saw them and said, 'Holy Toledo! What have they done to their countryside?'" That's what made a believer out of me," he said.

Shiny p Shiny lights, Shadows, Noise

Sue Silwinski of Sardinia, N.Y., writes (Sept. 27, 2035):

Over the past nine days and 3,000 miles and seven wind farms, Sandy Swanson and I took many still shots, reams of video, and copious notes and conducted numerous interviews. What's happening is an absolute crime. Every single impact that is denied by developers has been confirmed again and again in wind farm after wind farm. Lovely rural communities are being turned into industrial freak shows. In some places people have just accepted their fate and live with it, not understanding how empowered they actually are by their situations . . . meaning that all they'd have to do is get noisy enough and the developers would stop ignoring them. One told us she's learned how to go outside in her garden and block everything from her mind . . . so as not to be disturbed and frustrated. She said once, on a quiet day (the turbines weren't moving), she heard what sounded like gunshots. She had been blocking everything as she had taught herself to do and suddenly realized the gunshot noises were really coming from the nearest turbine . . . probably contracting as the sun went down.

Scott Smka from Lincoln Township, Wisconsin, is enduring such awful atrocities, it's very hard to believe they're true. I've even steered clear from his information over the past three years for fear of being accused of using scare tactics. But the guy is rock solid, and anyone who meets him and actually goes to his beautiful farm and sees his beautiful family knows he's the real deal. His neighbors know he's honorable and credible and that his troubles are real . . . it's those of us who hear about his dilemma long distance that doubt the truthfulness when we hear about his deformed cows, his family's health problems, etc. due to severe stray voltage.

Most farmers experience some levels of stray voltage on their farms. But the extenuating circumstances on Scott's farm include a combination of surface rock, no substation for this particular wind farm, and the nearness of the turbines. He and one other dairy farm are being severely impacted, but the other one, right next door, won't admit it because they own the leases for about 10 or 15 of the turbines and don't want to jeopardize that easy money.

Scott is a young man and the farm was his father's and grandfather's before him, but after hundreds of thousands of dollars in expenses to try to remedy the problems caused by the wind farm across the street, he's calling it quits and may be moved out by spring. His wife is pregnant with their third child and they are nervous wrecks, though they have gone through every imaginable test to ensure that the baby's been fine right along. He says with the equipment he's installed he knows when it's bad, and when it is they leave the home for a week, maybe two . . . however long it takes to get back to more tolerable levels. Scott says that under the

current conditions, he's losing about a thousand dollars a day from what his farm should and would otherwise normally produce.

Bob Bittner [Illinois], a long-time and dedicated opponent who we recently haven't heard much from, was not at home when we visited his lovely farm house . . . also once his father's, now surrounded with 10 turbines within 4,000 ft of his home, with one only 1,300 ft away. His neighbors told Sandy and I that they believe he spent over \$250,000 in court battles and ended up signing a deal with the developers that basically said he would quit interfering in exchange for not being sued for all the lost income the company incurred over the 3 or 4 years of legal wrangling he brought.

I left a note in his door, and when I got home there was an e-mail from him for the first time in a very long while saying that since the turbines went up, he and his wife, Sharon, for their peace of mind bought a cabin in the woods about seven miles away to escape the impacts . . . noise, lights shadows . . . People everywhere are being driven from their homes.

In the Mendota Hills wind farm [Illinois], it's like the twilight zone. There is no life. Almost every home within the boundaries of the wind farm is kept to look as if someone lives there . . . but on close inspection it's clear that no one does. All the lawns are mowed perfectly . . . but most often no flowers are tended. Every house seems to have a chair or two outside in the front yards creating the appearance that people actually plunk their butts down in them to relax once in a while, but they're dirty and unused. Every window and door is closed, with drapes and shades drawn at eye level. There are cars and trucks with current licence plates parked outside of garages or with garage doors open so you can see them. We didn't check for cobwebs in the mailboxes, we wish we had, but they looked rusty and old. Even dogs were kept on leashes in many of the side yards . . . animals that are evidently being visited once a day to be given food and water. I know this all sounds crazy, but to prove it to ourselves, we went back after dark . . . thinking, well maybe everyone was just at work. But inside these houses, only one light burned, shining through greasy grimy windows in spots where curtains were left slightly open to reveal the condition of the glass, and revealing absolutely no movement whatsoever.

We heard about connectors that were not supposed to be used, but were indeed and have since blown holes -- small craters -- in roads and fields. The stories we've been told all echo each other. There are many children involved. Some, such as in Lincoln Township, have grown up knowing nothing but life with wind turbines. People have been bought off where they're fighting. A family's teenage daughter totaled her car in an accident with wind equipment on a foggy day and then had to fight to get reimbursed! Another says that her little kids are terrified by the noise and can't fall asleep when conditions are bad, such as on rainy nights. Their nearest turbine is 1,000 feet from the bedroom window. Another older

woman says, through tears, that her town, where she was born and raised and where her family farm still exists, has been ruined.

Story after story after story

Lights, shadows, noise, TV and phone interruption, gawkers, accidents, lost views and plummeting property values, and more . . . all on tape, video, and still shots. We felt sick at the end of every day . . . like we had to get away and take a break from the twirling blades and the surreal atmosphere and our sadness for all these families.

It felt so good to get home and step out of the car into this beautiful environment that Sardinia still is and hopefully will stay for years to come. So . . . now we have to figure out how best to use all this information, and not let a smidgen go to waste, because all these families living in these inconceivable conditions deserve no less.

Industrial wind, corporate vandalism

Joanna Lake, March 30, 2005

Originally published in the Burlington (Vt.) *Free Press*, April 3, 2005

Also published as a letter in the *Vermont Guardian*, April 8, 2005, and the *Caledonian-Record*, April 16, 2005

Many well intentioned people champion industrial wind power, but it baffles me when those who label themselves "environmentalist" or "green," or who otherwise consider themselves to be politically progressive, seem so eager to do business with the same huge profit-driven corporations that have already done so much to destroy the planet. GE, one of the biggest manufacturers of military weapons and nuclear power plants, is also the US manufacturer of industrial-size wind turbines. GE got into the business by buying the wind division of the Enron corporation. War profiteer Halliburton is involved in the construction of offshore wind facilities in Britain. Investment banks such as Goldman Sachs and JP Morgan Chase own wind energy companies, as reported by the *New York Times* on March 22. Citizens for Tax Justice, a labor and consumer rights group, has noted that FPL Group, the parent company of the biggest wind energy company in America, paid no federal income tax in 2002 and 2003 on more than 2 billion dollars of profit, thanks in large part to the tax evasion schemes of industrial wind.

Blasting Vermont's lovely ridgelines to ram monstrous turbine assemblies into the earth, along with clearcut wide strong roads through wild areas and ever more power lines strung about, is a violent assault, despoiling all life around it. There seems remarkably little concern from the pro-industrial wind crowd regarding the further loss of habitat for other species and the inevitable deaths of many birds and bats. It seems that the big-wind supporters have bought into the rapacious corporate mindset of "think big." The US government is granting subsidies for industrial wind not because it gives a damn about green energy but because it benefits corporate America, as always. It is the same mentality, ironically, that applauds drilling for oil in the pristine Alaskan wilderness.

What ever happened to "small is beautiful"? Vermont is a small state. Why not instead promote small windmills, such as at the Danville School? We could advocate for and more generously subsidize even smaller windmills for home use along with solar panels, microhydro, and insulation to save heating fuel, as the purchase and installation of most of these things are beyond the means of many Vermonters. What about the use of biodiesel from non-genetically modified crops? Why aren't unnecessary recreational gas-guzzlers and polluters heavily taxed instead of relentlessly encouraged? Why are SUVs not required to be more environmentally friendly? Conservation would save much more energy

than giant wind facilities could ever generate. Alas, none of this will happen easily, if at all, because it won't benefit big business.

We have made a dire mess of this planet, and trashing and industrializing Vermont's mountains is simply adding to it. And the saddest part is that industrial wind facilities won't close down one fossil or nuclear fueled power plant after all that "necessary" destruction of Vermont's most valuable resource. The gargantuan turbines will be only an empty symbol for those people who need to easily assuage their consumerist guilt, most of whom will probably not be living anywhere near the noisy brightly lit monsters.

I sometimes wonder if the "progressive" supporters of big wind realize exactly what they are opening the door to and who will be profiting from the further industrialization of Vermont. Though there are no easy answers or quick fixes, we need to step back from the abyss of this high-testosterone approach and try to create more peaceful, imaginative, harmonious, and decentralized ways of employing renewable energy in Vermont.

Wind Energy's Colossal Profits at the Taxpayer's Colossal Expense

A Study for New York State

February 7, 2006

* jump to the bottom of the page ([Bottom Line](#)) if you don't care to wade through all these calculations ...

Major (though not exclusive) sources of profit for the wind energy companies in New York State (NYS)

... let's assume a 100 MW windplant. This amounts to 67 1.5 MW turbines, which is what Noble Environmental is calling for in Brandon and Ellenburg and Clinton Townships (Clinton & Franklin counties). The rule of thumb each turbine costs about \$1.5 million to erect; hence we're talking about a \$100 million project for the wind con

... okay, on a \$100 million project, with a 5-year, non-linear depreciation schedule (one of the incentives granted federal & state governments), the wind companies can depreciate:

- \$20 million the first year (20% write-off) = \$8.7 million tax savings
- \$32 million the second year (32% write-off) = \$13.9 million tax savings
- \$19.2 million the third year (19.2% write-off) = \$8.4 million tax savings
- \$11.5 million the fourth year (11.5% write-off) = \$5 million tax savings
- \$11.5 million the fifth year (11.5% write-off) = \$5 million tax savings

(There is an obvious incentive to sell the wind project after 3 years operation) The federal corporate tax rate is New York State's is 8.5%, so that's 43.5%. Hence, if the wind energy company is taking \$20 million off the top (gross) income the first year, that's a tax savings (shelter) of \$8.7 million in year 1. This figure goes up substan year 2 (\$13.9 million), drops back down to \$8.4 million for year 3, and dips down to \$5 million for years 4 & 5.

... then there's the federal Production Tax Credit of 1.9 cents/kWh. Multiply 24 hours x 365 days x 0.3 (for 30% efficiency) = \$4.9 million ... let's say \$5 million from the federal government.

... the wind company then sells its electricity to the power grid (NYISO) at 3 cents/kWh (approximately the going rate) thus making another \$7.8 million

... then we have the Renewable Portfolio Standard production incentive with the New York State Energy Research & Development Authority (NYSERDA), which appears to be 2.25 cents/kWh. (By way of explanation, the wind companies each sign a contract with NYSERDA, agreeing to sell to the NY grid, whereupon NYSERDA then gives the wind companies this 2.25 cents/kWh production incentive.) This works out to another \$5.9 million

Total profit:

.. assuming 30% turbine efficiency (a generous estimate, one routinely given by the wind energy companies themselves), the first year profit for a 100 MW (67 turbine) project comes to, at a minimum, \$18.7 million (from sales + federal Production Tax Credit + NYSERDA credit) + \$8.7 million in tax savings = \$27.4 million in year 1

*Lack of
Efficiency*

① *The following letter from Realtor Russell Bounds to the Maryland Public Service Commission outlines in stark terms how industrial wind turbines do, in fact, dramatically lower property values

Calvin Luther Martin

David Shipman, Esq.
Williamsport, PA

Effect on Real Estate

Dear Mr. Shipman,

I have been a full time realtor in Garrett County, Maryland for 13 years, with a sales volume over 100 million dollars, and rank as one of the most successful realtors in this area. I specialize in Rural Property Sales - specifically recreational property, woodland tracts, farms and mountain views.

I have recently testified in a Maryland Public Service Commission wind plant hearing as an expert witness regarding property devaluation caused by possible wind plant development.

Over the last two years, I have had more than 25 prospective buyers look at property in areas within 15 miles of proposed wind plant development. These properties are rural, mostly farms, cabins and mountain view homes and rural home sites.

As a realtor, I am obligated to disclose everything I know that may have a positive or negative impact on property. With respect to the possible development of wind power plants in this area, this is what I've disclosed to those prospective buyers: There are two proposed wind plants to be located along approximately 20 miles of Backbone Mountain, the prominent ridge that is the dominant geographic feature in the area. The proposed turbines are over 400' tall and may be noisy and produce shadow flicker over the land—large-scale light and dark strobing effects-- depending upon the way the sun shines through the turbines' blades. I have seen how wind plants near Meyersdale, Pennsylvania have altered the beauty of the natural views and disrupted the quiet enjoyment of property, resulting in major property devaluations there.

After this disclosure, not one prospective buyer made any offer for these properties, although they did purchase properties elsewhere.

Sincerely,

Russell Bounds
Realtor

Wind farm discussion at April Town Board meeting

Now that I've finally finished what happened at the EMC meeting on the Cornell wind farm, I'd like to report what happened at the April Dryden Town Board meeting the next night.

During citizen's privilege, Bill Openshaw read a prepared statement:

At the last Town Board meeting, we presented a petition urging the Board to amend the zoning laws to prevent the construction of large windmills anywhere in the Town of Dryden. We also brought each of you an information pack pertaining to our wind turbine concerns. I hope you have found some time to review that material.

Since the March meeting, I and my neighbors have been going door-to-door, informing other folks what Cornell is planning. We have also made phone calls to different Cornell departments who have an interest in the Mount Pleasant area. What we have discovered is that practically no one, including the affected Cornell departments, had any knowledge of Cornell's wind turbine farm plans. After being informed, the overwhelming reaction to this news was that of surprise and dismay. People can't believe Cornell would even consider this defiling of one of the county's very special natural areas. But at the same time, the prevailing public sentiment is that Cornell has come to expect that it can do whatever it wants.

I've attended two information meetings in the last couple of weeks. The first was at my home, with Cornell and a small group of neighbors. The second meeting, which was well-attended, over a hundred people, was held a week ago at the Varna Community Center.

In both cases, Cornell did their best to minimize our concerns and fears. Cornell had large posters on display in which they incorporated what I consider trick photography, which gave the illusion that these 400-foot wind turbines weren't really that big. Cornell did acknowledge that these structures would have to be equipped with flashing strobe lights, that these lights were most visible only at night. And yes, Cornell said there is a flickering shadow effect, created by the sun and the propeller blades, but it really depends on where

you are, how bad that effect would be.

If you're on the Cornell campus, it's not really a problem at all. On the issue of noise, Cornell said not to worry - the new improved turbines are not as loud as the old ones. Cornell assures us they are looking into the bird and bat mortality issue. They have contracted their own in-house Lab of Ornithology to make the determination. Coincidentally, in California, many wind turbine farms are shut down because of lawsuits involving bird and bat mortality.

Also, Cornell has told us not to worry about the wind turbines close proximity to the landing flight path of the airport. According to Cornell's interpretation of the FAA regulations, it's not a problem. Interestingly, though, the chief flying instructor from East Hill Flying Club stood up at the Varna meeting and stated, in his opinion, putting up eight 400-foot wind turbines on Mount Pleasant seriously jeopardizes the safety of the airport.

We are here again this evening to present you with the same petition, this time with what we hope you will a significant number of signatures: over 400. It is signed by many folks who love living on Mount Pleasant. The rest of the signatures are from people who love Mount Pleasant for a multitude of other reasons. We are counting on you to prevent Cornell from making this unethical self-service mistake in the Town of Dryden.

Town Board member Chris Michaels was the first to speak, saying that "my understanding of current town law is that our zoning does not allow that use." Zoning Officer Henry Slater concurred. The use isn't specified under the zoning law, and unspecified uses are prohibited by default.

Michaels continued by saying "They can't do it if they're complying with our zoning law.... obviously they've got something in mind, or are planning to come to us. If they act under the state college do they [need to conform to] our zones?"

Town Attorney Mahlon Perkins suggested that "it's an open question." Michaels noted that Cornell had submitted to the City of Ithaca's processes.

County Legislator Martha Robertson pointed out that Cornell was just doing a feasibility study now, and that Cornell would begin more formal processes once that was complete. "I don't think there's any contemplation of getting around the approval process," she said, "but I think we've all seen that they have a lot of firepower if they really want to get a variance for a particular zoning issue. But at this point they're not ready to come to you for approval or a variance, because they're just not sure it's worth it."

Supervisor Steve Trumbull reported that Cornell had said that "if Dryden denied them, they'd stop right there."

A speaker told of a moratorium on windfarm development after they'd been permitted because of a fall in property values of up to 27%. Legislator Robertson replied that

They did talk about, that in many cases, a project like this, the developer would make some payment to the municipalities: county, school district, town, whatever, in sort of compensation for essentially the use of the wind. That doesn't do anything particular for homeowners, except lower everybody's property taxes. But I think the point is that this is pretty preliminary, and they did, as you say, Steve, say at that meeting in Varna that the answer was "we'd stop if we didn't get a variance," which is significant because they've

Dryden

Semmler

taken other projects through the courts, through lawsuits.

When asked if Cornell had come before the board, Supervisor Trumbull replied that all they'd had were letters. Resident Avery Park asked what power the town had over the project, and Trumbull reiterated that it would take "a use variance, if we agreed to it, but I don't see it happening." Park encouraged the board to imagine walking out their front doors and seeing 400-foot towers, and Trumbull replied that "I wouldn't like it."

John Semmler said that Cornell had come to their meetings and claimed that their property values would increase, but Semmler believed that was only possible because property values had already decreased because of the announcement of the project. Semmler told of his visit to the Fenner wind farm site:

It scared the hell out of me. It really did. It's noisy - I don't care what they say about not hearing it, well, I don't hear a thing right now when I walk out my door. I hear birds, and trees rustling, beautiful sounds, and you go up there, and you hear, when these things turn to face the wind, there's like a train on a railroad track. It's the only way I can describe it, metal on metal. The blades whirl around. You get what would be like a fluorescent light hum from the generator, this thing that's the size of a school bus that sits up on top of the tower. I would hate to see these in the Town of Dryden, anywhere. Call me a NIMBY, I don't want to agree, but I'd hate to see it in anybody's back yard.

The other thing I'd like to bring to your attention is the financial implications. It's not all that clear, and I don't think Cornell is making that that clear, I respect Martha's view on this, but I think there's a lot more than just feasibility stage right here. I think we're seeing Cornell digging in, doing some things. I think they were sincere about saying they would stop when it reached the Town Board, and they know you're not going to approve it - come on. Why are they going to all these meetings, and putting all this energy, and building an anemometer, you know - I don't think this is feasibility. I think they've got a plan. So I'm not as confident that that's not going to happen.

The financial part of it is, there are state grants available for the construction of these facilities, our state tax dollars. There are federal subsidies for what they call production credits, our federal tax money. To me, there's something inherently wrong with everybody in this room paying Cornell's utility bills. If it were nothing else than that, I don't care what kind of power it was, I would think that that's a travesty. What the hell are we doing that for?

The other thing is that they keep saying that there isn't going to be any effect, everything we read says no effect on health, and environment, and all of that. Well, they admitted at the [EMC] meeting last night... that they get all of their data from the wind energy coalition, and the turbine builders, General Electric being the big one. They're in bed together, believe me. There's no question. They need to be reading some other stuff and I would encourage you to look at some other stuff too.

I think if it weren't for the financial incentives they never would have gotten into this. I don't think this is about Kyoto Now, I really don't. I think it appeases the students, and you know, makes them look like good citizens, but I think there's a whole other scenario that's behind the scene there.

The other thing is there's a principle that New York State is adopting, called the

Precautionary Principle, and it has to do with the development of projects, developers and the responsibility that developers have. It's sort like, if you don't know what the outcome is going to be, the burden of proof is on you to prove that it's not going to be harmful, that it's not going to be detrimental, or whatever. I think so much of what we're hearing right now is "Well, we understand this won't happen, we don't think it's going to be a problem, we're looking into that." You know, there's really a lot of unanswered questions.

I just hope whatever happens, we hold their feet to the fire, because there are a lot of people impacted, and I think one of the most beautiful areas in the Town, and I'd just hate to see it littered up. I said to somebody today, I pick up beer bottles out of the ditches alongside of my house there, and this is just another piece of trash, a big beer bottle.

Councilman Christofferson asked if Semmler had talked to anyone in Fenner, and he replied:

No, I didn't knock on any doors. We've got reports from a couple of people - I'm glad you brought that up - because a lot of these people that love the wind farms are getting \$5000 a year lease payments, and they want more of them. They're not going to say to the power company or the town, or anybody, "this is horrible," because that's a nice sum of money, five thousand bucks. People that aren't getting paid and live near them - there's some material I think we gave you last time, which Bill handed out, and it paints a pretty sorry picture.

Legislator Robertson mentioned that "Cornell is taking a bus, or as many buses as needed, up to this wind farm on May 14th, that's a Saturday. I guess they're saying 9 to 3... if anybody's interested, get in touch with me and I'll get the names to the right people."

Semmler noted that:

It's not a bad drive about an hour. I would encourage you to go up... the Cornell thing is going to go to the sites, which, I think, are the least offensive, and all of that. I'm not trying to sound paranoid here, but I think they're taking orders from their energy consultant on this, AWS Wind Power... I would encourage you to go up there, it's maybe an hour fifteen or twenty... on your own. Drive right up to the base of some of these, stand there and listen to them, go over around various places, because the noise and the effect of these depends on the lay of the land. It's not always the same in all the places. You can be a quarter of a mile away, maybe, Dan mentioned that earlier, and not hear anything. But maybe you can be a mile away and hear it all the time.

There was another brief discussion at the very end of the meeting, when Town Councilman Steve Stelick warning that:

we need to be proactive with this possible wind turbine. I agree that Cornell's moving along. Why would you continue on with something when you know that, from what I can tell, we don't allow this kind of use. Why would you continue on with that unless there's this desire to complete this project? I just think that we need to be a little bit more proactive... we don't want to be waiting until the last second when they come forward with whatever the proposal is. I think they're spending a lot of money, to come up with all of this.

Legislator Robertson wanted Cornell to discuss alternatives to the approach they were currently taking, like buying alternative energy power from other locations. Environmental Planner Debbie Gross said

that the Conservation Advisory Board was also discussing it. Resident Avery Park suggested not letting Cornell build its case, but Town Attorney Mahlon Perkins warned that "the safest course of action is proactive." Councilman Hattery especially wanted to get their comments on the record.

"Big money" discovers the huge tax breaks and subsidies for wind energy while taxpayers and electric customers pick up the tab

Glenn Schleede, April 14, 2005

[Introduction](#)

- Recent events confirm that "big money" interests in the US and Europe have discovered the enormously generous tax breaks and subsidies that are now available in the US for producing electricity with wind turbines. These organizations are moving aggressively to build "wind farms" and to seek more subsidies.

Meanwhile, as more wind turbines are proposed in the US and other countries, ordinary citizens have learned that "wind farms" are not environmentally benign. Instead, wind energy has high economic, environmental, ecological, scenic and property value costs. Wind turbines produce only small amounts of electricity and that electricity is unreliable and low in value.

Quite likely, many members of Congress, state legislators, governors, regulators and local officials don't yet realize that they have been misled about the true benefits and costs of wind energy – or the extent of their combined generosity to the wind industry.

In the US, "wind farms" are now being built primarily for tax avoidance purposes, not because of their environmental, energy or economic benefits. The tax breaks and subsidies have more value to "wind farm" owners than the revenue from the sale of electricity they produce.

These generous tax breaks and subsidies are at the expense of ordinary taxpayers and electric customers and are hidden in their tax bills and monthly electric bills. Government officials seem unaware or uncaring about either the large transfer of wealth to "wind farm" owners from ordinary citizens – or the fact that large amounts of capital are being spent on projects that produce only small amounts of unreliable, low value electricity.

As detailed below:

- At least 10 large US and foreign companies are now working to build more "wind farms" in the US to take advantage of the exceedingly generous tax breaks and subsidies.
- Facts demonstrate that advocates have consistently overstated the environmental benefits and understated the environmental, ecological and economic costs of wind energy.
- The tax breaks and subsidies for wind energy already in place are providing huge benefits for a few companies but the wind industry is lobbying for even more.

Despite the facts, it's far from clear that legislators, local government officials and regulators will temper their enthusiasm for wind energy since so many have accepted as fact the false and misleading information distributed during the past decade by wind energy advocates. Also, they are well aware of wind industry lobbying power and campaign contributions.

Recent evidence of big money interest in wind energy tax breaks and subsidies

As indicated above, a number of large US and foreign companies (apparently with income to shelter from taxation), as well as law firms and lobbyists, have become aware of the enormously generous federal, state

and local tax breaks and subsidies available for wind energy in the US.

Presumably these firms are well aware that the government largess they are pursuing is at the expense of ordinary taxpayers and electric customers, but there is no reason to expect that they would work to protect the interests of either of these broad groups. Instead, their interests are in taking advantage of government measures to reduce their taxes and to increase their profits.

Most of the "Big Money" organizations are in the energy and financial industries, including one firm that recently paid a large fine relating to its work with Enron. Notably, Enron also took advantage of unwise government policies at the expense of taxpayers and consumers. Now, other big firms are taking advantage of a government-created "wind energy money machine."

The following examples illustrate the enormity of the tax breaks and subsidies and/or the extent to which big money organizations are pursuing those generous tax breaks and subsidies.

1. FPL Group apparently paid NO federal income taxes in 2002 or 2003 while reporting net income of more than \$2 billion.³ Those are the years FPL Group's subsidiary, FPL Energy (currently the largest owner of wind generating capacity in the US and sister of Florida Power & Light Co.), invested heavily in wind generation ("wind farms"). Apparently FPL Energy took more than \$1.2 billion in depreciation deductions in those years.⁴
2. General Electric bought Enron Wind's wind turbine manufacturing business⁵ in May 2002, with the intention of capturing a large share of the artificial market for wind turbines created by the tax breaks and subsidies in the US and other countries.
3. Gamesa, a Spanish manufacturer of wind turbines and developer of "wind farms" in several countries, in September 2002 acquired 75% of the stock of Navitas, a Minneapolis-based developer of "wind farms." Gamesa companies apparently are proposing "wind farms" in Wisconsin, Illinois, Pennsylvania, and states in the Southwest. In early 2005, Gamesa announced plans to begin manufacturing wind turbine blades in Pennsylvania.
4. Midamerican Energy, 80.5% owned by Warren Buffet's Berkshire Hathaway,⁶ has also found the huge tax breaks and subsidies available for "wind farms." Last year, Midamerican completed roughly half of its originally planned 310.5 megawatt (MW), \$323 million wind energy project in Iowa, which is being expanded to some 360 MW and \$386 million. The Omaha World Herald has reported that Midamerican will reap roughly \$300 million in tax benefits over 20 years from the project due to the federal Production Tax Credit, (\$175 to \$195 million) and forgiveness of

Iowa property tax (\$130 million).¹

Under the federal accelerated depreciation rules applicable to wind energy, Mid-American should be able to deduct its entire \$386 million capital investment from otherwise taxable income during the 2004-2010 tax years, thus reducing its federal tax liability by about \$135 million during those years.² Those depreciation deductions from income can carry through and reduce Iowa corporate income tax by about \$46 million during the same years.³

5. American Bar Association, in mid-2004, established a "Renewable Energy Resources Committee."⁴ During a December 15, 2004, teleconference, Ed Feo of Milbank Tweed Hadley & McCloy, LLP pointed out that 2/3 of the economic value of wind projects come from tax breaks.⁵

6. AES Corporation, on January 11, 2005, announced acquisition of SeaWest Holdings, Inc., parent company to, among others, SeaWest WindPower, Inc. which has "nearly 500MW of wind facilities throughout California, Wyoming and Oregon" and "has site control of 1,800 MW of development sites in ten of the western United States."⁶ In 2004, AES invested in US Wind Force, LLC, which is developing "wind farms" in certain mid-Atlantic states. On April 5, 2005, AES announced that it had entered into a joint venture with EHN to develop wind energy facilities in the State of New York.⁷ EHN (Corporación Energía Hidroeléctrica de Navarra, S.A.) was acquired in January 2005 by Acciona, a conglomerate with headquarters in Madrid, Spain and a variety of operations in many countries. EHN is described by the company as one of "the largest wind energy developers in the world. The company owns "wind farms" in Spain, Germany, France and the US.

7. PPM Energy, US subsidiary of Scottish Power, on January 4, 2005, announced its purchase of Atlantic Renewables and its wind development portfolio. Atlantic Renewables, an aggressive "wind farm" developer, previously, had sold off its "wind farm" projects to large organizations such as FPL Energy/FPL Group (which, as shown in 1, above, has profits that could be sheltered with federal and state tax breaks). PPM currently has 830 MW of wind generation in operation in 7 states and "has a goal of bringing 2,300 MW of new wind power to market by 2010."⁸

8. J. P. Morgan has surfaced as the organization financing Noble Environmental Power LLC, an organization with an office in Connecticut that is seeking to build "wind farms" in New York, Connecticut and Michigan. Noble Environmental Power, LLC ("Noble") has wind projects comprising more than 1,000 MWs in active development. Noble intends to retain ownership of the wind projects it develops. Noble is seeking to bring on line one or more wind generation facilities before the end of 2005.⁹

9. Goldman Sachs announced on March 21, 2005, that it is acquiring

Zilkha Renewable Energy of Houston Texas. Zilkha is an "independent wind energy development company, with a portfolio of nearly 4,000 megawatts in various stages of development in a dozen states. Goldman Sachs will acquire 100% of Zilkha's interests in the 200-megawatt Flat Rock Wind Power Project in Lewis County, New York, as well as 100% of Zilkha's interest in the 150-megawatt Blue Canyon Phase II Project in Oklahoma, both of which are expected to be completed by the end of 2005. [Zilkha is now known as Horizon. – Ed.]

10. Enxco is an affiliate of EDF Energies Nouvelles, a member of the EDF (Électricité de France) Group. Enxco develops, constructs, operates and manages wind energy projects and proposes to build "wind farms" in several US states, including Washington, Idaho, West Virginia and Massachusetts.

11. Numerous smaller companies have undertaken the "on the ground activities" to force "wind farm" projects through state and local government zoning and permitting process. Often, they sell their projects off to larger organizations with profits to shelter from taxation.

12. "Renewable" energy advocates, including wind advocates, have created a variety of profit-oriented and nonprofit organizations and signed up various Washington DC-based "law" firms and lobbyists (including former White House and CIA officials) to press for continuation and expansion of lucrative tax breaks and subsidies for wind energy, including the insidious "Renewable Portfolio Standards." Additional lobbying power has come from a variety of organizations that plan to make money on trading of Renewable Energy Certificates (sometimes called "Green Tags") that have been created by several states that have established "Renewable Portfolio Standards" and renewable energy credit schemes.

Facts about wind energy are just beginning to catch up with the false and misleading information that has led to faulty government policies, tax breaks and subsidies

While government officials lavish tax breaks and subsidies on the wind industry, ordinary citizens around the world where "wind farms" have been built or are proposed are learning that the public, media and government officials have been badly misled about the costs and benefits of wind energy. As the facts are becoming known, opposition to "wind farms" is growing rapidly in US and other countries, including the UK, Germany, Denmark, Spain, Italy, France, Australia and New Zealand. Some 300 citizen-led opposition groups have emerged.

These groups face an uphill fight in getting government officials to understand, accept and act on the facts about wind energy because the

wind industry and other wind advocates have, for more than a decade, distributed false or misleading information to the public, media and government officials. The U.S. Department of Energy (DOE) and its National Renewable Energy "Laboratory" (NREL) participate in distributing such information – at taxpayer expense.

There are at least 10 major reasons why "wind farms" have become controversial. These points are explained in other papers²² and web sites and will only be described here briefly.

1. Tax avoidance – not environmental and energy benefits -- has become the prime motivation for building "wind farms." The most important and lucrative tax breaks and subsidies are listed later. Briefly, the tax breaks include federal and state accelerated depreciation, production tax credits, and reduced or forgiven property and sales taxes.

2. Huge windmills -- often taller than the US Capitol – produce very little electricity. Some 15,000 windmills are now scattered across thousands of acres of land in 30 states in the US, with total generating capacity of 6,740 megawatts (MW) as of January 5, 2004.²³ If those thousands of windmills average a generous 27% capacity factor, the total amount of electricity they would produce annually would be 15,941,448,000 kilowatt-hours.²⁴ That sounds like a lot of electricity, but it is equal to 41/100 of 1% of the electricity produced in the US during 2003.

3. Electricity from wind turbines has less real value than electricity from reliable generating units, and they detract from electric system reliability. Wind turbines produce electricity only when the wind is blowing within the right speed range. Today's models may begin producing some electricity at wind speeds of about 8 miles per hour (MPH), reach rated capacity around 33 MPH, and cut out around 56 MPH. Because their output is intermittent, volatile and largely unpredictable, the electricity they produce has less value than electricity from reliable ("dispatchable") generating units.

Electricity grids must be kept in balance (supply & demand, voltage, frequency), so some reliable, dispatchable generating unit(s) must be immediately available at all times – and operating at less than peak efficiency and capacity -- to "back up" the unreliable wind generation. The reliable, backup unit(s) must ramp up and down to balance the output from the wind turbines. Wind turbines detract from grid reliability and would be of no value in restoring an electric grid when there is a blackout. Further, when electricity demand increases, reliable units must be added to meet growing electricity demand even if wind capacity has been built. Wind turbines have virtually no "capacity value." Thus, electric customers pay twice; once for the wind energy and again for reliable capacity.

4. The true cost of electricity from wind is much higher than wind

advocates admit. Wind energy advocates ignore key elements of the true cost of electricity from wind, including:

- The cost of tax breaks and subsidies which shift tax burden and costs from "wind farm" owners to ordinary taxpayers and electric customers.
- The cost of providing backup power to balance the intermittent and volatile output from wind turbines.
- The full, true cost of transmitting electricity from "wind farms" to electric customers and the extra burden on grid management.

5. Claims of environmental benefits of wind energy are exaggerated. The wind industry typically overstates claims of potential emission reductions that might result from displacing electricity generated by fossil-fueled generating units. They tend to ignore the fact that backup generating units must be immediately available and running at less than their peak efficiency or in spinning reserve mode, and that backup units continue to emit while in these modes. Also, the generation that may be offset may not be powered by fossil fuels. Further, under "cap and trade" programs, credits for sulfur dioxide or nitrogen oxides emissions that are displaced by wind could be sold to other emitters, with NO reduction in those emissions.

6. "Wind farms" have significant adverse impacts on environmental, ecological, scenic and property values. Citizens in various states (and other countries) where "wind farms" have been constructed have become painfully aware that – in addition to the high true cost of the electricity – "wind farms" impair environmental, ecological, scenic and property values. Among the adverse impacts are noise, bird kills, interference with bird migration paths and animal habitat, destruction of scenic vistas and ecological rarities (such as the Flint Hills and Tallgrass Prairie in Kansas), distracting blade "flicker" and aircraft warning lights, and lowering the value of properties located near the huge structures.

7. "Wind farms" produce few local economic benefits and such benefits are overwhelmed by the higher costs imposed on electric customers through their monthly bills. DOE, the National Renewable Energy Laboratory (NREL) and the wind industry have falsely claimed that "wind farms" provide significant economic benefits in the areas and states where they are constructed.³⁷ They often claim benefits from the capital investment, jobs, tax revenues, lease payments to landowners, and "other" economic activities. Sometimes they claim increased tourist traffic.

In fact, as explained in detail elsewhere,³⁸ there are few economic benefits and these are overwhelmed by the higher true cost to electric customers and taxpayers of the electricity produced by the "wind farms."

8. Various other subsidies shift large amounts of cost from "wind farm" owners to ordinary taxpayers and electric customers. The wind industry benefits from subsidies in addition to the tax breaks mentioned above and described below. Among the other subsidies is DOE funding for wind energy R&D, and payments to "wind farm" developers provided by state governments (such as Massachusetts, New York, Wisconsin, Minnesota and California) using funds collected from electric customers via so-called "public benefit charges."

Other subsidies are in the form of artificially created, high price "markets" for wind-generated electricity. These include guaranteed markets for electricity result from (a) insidious "renewable portfolio standards" mandated by several states that require electricity suppliers to obtain some share of their electricity from "renewable" sources, (b) additional markets due to mandated purchases of "green electricity" by federal and state government agencies, and (c) state programs requiring or encouraging electric utilities to offer "green" electricity at premium prices. Electric customers can elect to pay premium prices but these programs generally do not attract enough "volunteers" to pay the utilities' costs of buying the "green" electricity and administering the program. The cost not recovered from customers paying premium prices is then spread across all of the utility's customers and hidden in monthly electric bills.

9. The big "winners" are "wind farm" owners and a few landowners who lease their land. Electric customers and taxpayers are the big "losers." First, as explained in more detail below, "wind farm" owners benefit enormously from the generous tax breaks and other subsidies that shift tax burden to ordinary taxpayers. "Wind farm" owners also benefit from the revenue from the sale of electricity while shifting costs (e.g., backup generation and transmission costs) to electric customers.

Secondly, a few landowners who lease their land may be "winners" but their neighbors are the "losers." For example, landowners who lease land at the rate of \$5,000 per MW of wind turbine capacity would derive income of \$500,000 per year. However, if that "wind farm" achieved a 30% capacity factor and the electricity cost consumers only an extra \$0.015 per kWh, the extra cost to electric customers would \$3,942,000 per year or nearly 8 times the income received by the few landowners. Thus, it would be cheaper for the electric customers to pay the landowners to NOT allow wind turbines to be built on their land!

10. The wind industry falsely claims that they deserve tax breaks and other subsidies because other energy sources have received even larger government-imposed benefits. Ideally, subsidies for all energy sources would be reduced significantly, but the wind argument is fundamentally flawed because it does not take into account either the existing or potential contribution of wind energy in supplying US energy

requirements. When the expected contribution of wind energy toward supplying US energy requirements is taken into account, wind energy is among the most heavily subsidized of all energy sources. EIA expects wind to provide less than 1/2 of 1% of US energy requirements by 2025.

The tax breaks and subsidies that are attracting big money interests to wind energy

As indicated above, the tax breaks and subsidies for the wind industry are at the expense of ordinary taxpayers and electric customers whose interests are not well represented in government circles. The practical effects of the tax breaks and subsidies are to:

- Misdirect hundreds of millions of investment dollars into energy projects that produce only small amounts of low value, low quality electricity.
- Transfer substantial wealth from ordinary taxpayers and electric customers to "wind farm" owners by shifting tax burden from "wind farm" owners to ordinary tax payers, and passing along the high priced electricity from "wind farms" to electric customers.

Among those tax breaks and subsidies are the following.

1. *Federal Accelerated Depreciation.* One very generous subsidy available to companies with income to shelter is 5-year double declining balance accelerated depreciation (5-yr.; 200% DB) that can be used to calculate depreciation for tax purposes. This is one of the depreciation schemes permitted by the IRS under the label "MACRS," Modified Accelerated Cost Recovery System. Five-year 200% DB can be used for capital costs of facilities using wind to produce electricity for sale. Nearly all other electric generating facilities must use 20-year depreciation, so "wind farm" owners are receiving a tremendous benefit.

In those states that "conform" their corporate income tax to the federal system, a depreciation deduction from otherwise taxable income carries through to the corporation's state income tax returns.

Determining the exact amounts of accelerated depreciation deductions would require access to details of a corporation's taxes. However, as indicated on page 2, above, Warren Buffet's Midamerican Energy should be able to deduct from taxable income its entire \$386 million capital investment in its 360 megawatt (MW) "wind farm" in Iowa during the period from 2004-2010. Assuming marginal tax rates of 35% for federal and 12% for Iowa corporate income tax, the depreciation deductions would reduce tax liability by \$181 million during the period from 2004-2010. That is in addition to the roughly \$300 million in tax benefits over 20

years from the project due to the federal Production Tax Credit, (\$175 to \$195 million) and forgiveness of Iowa property tax (\$130 million) reported by the Omaha World Herald article referred to earlier.

It's important to note that if a "wind farm" were sold to a new owner after the accelerated depreciation allowances were used, the new owner would also be able to utilize the generous accelerated depreciation benefits to "recover" its capital investment.²⁶

2. Federal Production Tax Credit. The second generous federal subsidy available to "wind farm" owners is the Production Tax Credit of \$0.019 per kWh of electricity generated during the first 10 years of a wind project's life. For example, at the current rate of \$0.019 per kWh, owners of the proposed 150 MW Elk River "wind farm" in Butler County would receive a tax credit (i.e., a direct deduction from its federal income tax bill) of \$9,986,400 per year if the turbines produce at an average 40% capacity factor (i.e., 150,000 kW x 8760 hrs. x .40 x \$0.019). The rate, originally set at \$0.015 per kWh, has just been adjusted upward for inflation, reaching \$0.019 per kWh, retroactive to January 1, 2005.

Organizations owning "wind farms" must have substantial taxable income from other sources to take advantage of the two federal tax shelters described above.²⁷ That is one reason why small "wind farm" development companies often sell off their projects to larger companies or find ways to "sell" the tax benefits.

3. Reductions in wind farm owners' state corporate income tax liability. Kansas taxes corporate income at a basic rate of 4% with a 3.35% "surtax" for income over \$50,000. The starting point in computing Kansas taxable income is the federal taxable income of the corporation. Thus the generous federal accelerated depreciation deduction described in paragraph 2, above, reduces the taxable income basis used before applying Kansas' 7.35% marginal income tax rate. This benefit is even greater in states with higher corporate income tax rates such as Iowa, with a 12% rate.

4. Property, sales and other state and local tax reduction or elimination. Thanks to the effectiveness of wind industry lobbyists, several states provide reductions or elimination of state or local property, sales or other taxes. These include New York, West Virginia, Wisconsin, Minnesota, South Dakota, and Kansas. In some cases, "wind farm" owners make voluntary payments in lieu of taxes to offset part of the revenue lost by state and local governments as a result of the exemptions. However, such payments may not be adequate to cover the costs that will be incurred because of the facility, e.g., for road construction and repair, and police and fire protection. Often, such payments are offered only in the early years of a project to help gain public and political support for approvals needed to build the facility, whereas property taxes would continue for the

life of the facility.

5. *"Public benefit funds."* As indicated above, several states have added an extra "tax" (often called a "public benefit charge" on electric customers' month bills to create a so-called "public benefit fund." States with such funds include Massachusetts, New York, Minnesota, Wisconsin, and California. State officials use some of these funds to make payments to owners of wind or other "renewable" energy facilities. These payments are in addition to all the federal, state and local tax breaks described above.

6. *"Renewable Portfolio Standards" (RPS).* Such standards, in a variety of forms, have been adopted by about 17 states. Renewable Portfolio Standards (RPS) help increase consumers' electric bills in two ways.

First, they provide artificial, guaranteed markets for high priced electricity produced from renewable energy facilities, including "wind farms" assuring the owners of these facilities that they will not have to compete with prices of electricity produced from traditional energy sources, such as coal, natural gas, oil, hydropower or nuclear energy.

Second, a RPS typically establishes some minimum percentage of electricity sales that must come from "renewable" energy sources. The company selling the electricity to end use customers (often an electric distribution utility) can either generate the electricity from "renewable" sources, buy it from some firm that generates such electricity, or, perhaps, buy "renewable energy credits" (i.e., the scheme contemplated by the KEC) covering the amount of electricity needed to meet the percentage standard.

The higher cost of the electricity from "renewable" sources and/or the credits that the electric distribution company is forced to pay (instead of the lower cost electricity from traditional sources) is, in one way or another, passed on to electric customers in the form of higher bills for electricity – with the blessing of state public utility commissions. The wind industry is lobbying the US Congress to create a "national" Renewable Portfolio Standard and push additional states to adopt state standards.

7. *Mandated "green energy" purchases.* Other artificial "markets" are created for the benefit of "wind farm" and other renewable energy producers by federal and state executive actions and, in some cases, by state statutes. In these cases, federal or state government agencies and state funded colleges are required to obtain certain portions of the energy they use from "renewable sources" even though the energy requires payment of above market prices.

8. *"Voluntary" programs offering "green" electricity at a premium price.* Utilities in many states now have programs where customers are

permitted to volunteer to pay a higher monthly bill when the utility assures them that the electricity they are paying extra for is generated from a "renewable" energy source. In some states these programs are required by law, in others utilities are "encouraged" to create them by state utility commissions, governors or legislators. In still other cases, such programs are created by a utility as a way to show customers, the public, media or government officials that they are "environmentally conscious" – efforts that have become known as "green washing."

Relatively few electric customers volunteer to pay the required premium price, particularly if they realize that (a) their decision to do so would be largely symbolic and/or (b) that other actions, such as using more energy efficient light bulbs, are much more cost effective and environmentally meaningful. As in the case of "Renewable Portfolio Standards," the extra revenue generated by the premium price is generally not sufficient to cover the higher cost of the electricity and the cost of the staff that must be maintained by a utility to administer the programs. The utility's costs that are NOT recovered through the premium price are then passed on to all of the utility's customers.

9. *Other state utility commission actions that subsidize wind farms.* "Wind farms" are inefficient users of electric transmission capacity because the output from wind turbines is intermittent, volatile and largely unpredictable. The wind industry works to shift the cost of building transmission capacity from "wind farm" owners to electric customers. Some utility commissions (e.g., Minnesota) have permitted this to occur, providing an additional subsidy for "wind farms."

The wind industry is also seeking to have transmission capacity built in other states with the costs shifted to electric customers (and hidden it in their monthly bills). Special arrangements have also been made by other utility regulatory commissions and grid managers (e.g., Independent System Operators (ISOs) and Regional Transmission Organizations (RTOs)) that, in effect, provide additional subsidies to "wind farms."

10. *Industrial Development Bonds to finance privately owned wind farms.* A few states (e.g., New Mexico) have permitted "wind farm" owners to finance their projects using state backed bonds ("industrial development bonds"). Such bonds have interest rates that are lower than commercial financing, particularly because of their favorable tax treatment.

Conclusions

Clearly, the wind industry – with support from DOE and NREL, using tax dollars -- has been very successful in misleading the public, media and government officials about the benefits and costs of "wind energy." These advocates for "wind energy" have grossly overstated the benefits and

understated the costs but they have succeeded in gaining approval for tax benefits and subsidies that are proving to be enormous -- and very attractive to aggressive "big money" interests.

While the facts about the adverse environmental, ecological, energy and economic impacts are becoming clear, taxpayers and consumers face a difficult task in getting government officials -- executive, legislative and regulatory -- to understand the facts. They face an even more difficult task in getting policies changed. Many government officials apparently do not have the staff or other capability to check the validity of information provided to them by special interest groups.²⁵

Even when they learn the facts, few political leaders have the courage to eliminate bad policies when those policies are "guarded" by large, effective lobbies and large campaign contributions.

About the author

GLENN R. SCHLEEDE is semi-retired after working on energy and related matters in government and the private sector for over 30 years. He now devotes a large share of his time to self-financed analysis and writing about (a) government policies and programs that are detrimental to consumers and taxpayers and (b) government or private sector activities that are presented to the media, public and government officials in a false or misleading way.

From 1992 until September 2003, Schleede maintained a consulting practice, Energy Market and Policy Analysis, Inc. (EMPA), providing analysis of energy markets and policies. During that time he worked primarily on natural gas and electricity issues.

Prior to forming EMPA, Schleede was Vice President of New England Electric System (NEES), Westborough, MA, and President of its fuels subsidiary, New England Energy Incorporated. His time with NEES included responsibilities for procurement and transportation of coal, natural gas and oil for NEES facilities, NEES's oil and gas exploration and coal shipping ventures, and NEES economic planning and budgeting functions.

Previously, Schleede was Executive Associate Director of the U.S. Office of Management and Budget (1981), Senior VP of the National Coal Association in Washington (where he was employed from 1977-1981) and Associate Director (Energy and Science) of the White House Domestic Council (where he served from 1973-1977). He also held career service positions in the U.S. OMB and the U.S. Atomic Energy Commission. He has a BA degree from Gustavus Adolphus College and an MA from the University of Minnesota. He is also a graduate of Harvard Business

Schleede is the author of many papers and reports on energy matters. His articles appear in various journals and/or are covered in the energy trade press. Some appear in full text on various public policy group web sites. Since 2001, Schleede has analyzed and written a lot about wind energy. The facts (a) convinced him that wind turbines are a niche technology that would never make a significant contribution toward meeting US energy requirements, and (b) demonstrated that the US DOE's Office of Energy Efficiency & Renewable Energy (DOE-EERE); the National Renewable Energy "Laboratory" (NREL) and other DOE contractors, using tax dollars, distribute false and misleading information on wind energy.

Schleede has been a frequent target of ad hominem attacks by officials from the wind industry as well as NREL and other DOE-EERE contractors. Their attacks seldom deal with the substantive issues he raises. AWEA and other DOE funded organizations (using tax dollars that flow through DOE-EERE) have claimed falsely that Schleede works for fossil-fuel industries. In response, Schleede notes that their claims are false and that ALL his work on wind energy has been self-financed. He has offered leaders of the attacking organizations (including NREL) the opportunity to review all his personal and business financial records, provided that (a) the work is done by an independent third party who can assure appropriate confidentiality of information and (b) the work is paid for by the individual and organization making the charges and is not reimbursed by DOE or otherwise paid for by using more tax dollars.

Questioning the faith of wind power:

David Roberson, March 17, 2005

Originally published in the Shelburne Falls (Mass.) *Independent*,
December 23, 2004

Development of wind power plants is swiftly becoming the most critical rural conservation and land-use issue of our time. But many who support wind power are sadly unaware of the technology's serious impacts and have accepted on faith the seductive vision offered by the industry: that wind power is clean, green energy.

We are led to believe that construction of wind plants is progressive and ecologically responsible development that will lessen our reliance on foreign oil and reduce global warming. Opponents are often dismissed as elitists who care more for the appearance of the landscape than for saving the planet. For some folks, it seems, if you aren't into wind power then you are an "anti-environmentalist." That is untrue, and I find it disturbing that this attitude seems so prevalent.

I don't like to represent myself as an exemplar of any green ideal, but I feel a deep personal connection to nature. My wife and I garden organically, raise much of our own meat and dairy, and try to live simply and sustainably. We heat our home almost exclusively with wood that I cut on our land.

When we left our rented home in Hawley, where we lived for 12 years without AC electricity, and moved to Rowe, one of my first thoughts was to put up a wind generator, get some batteries and an inverter, and continue to live independent of the power company.

After I pondered and researched the matter, I came to feel that erecting a wind generator to power my grid-connected house would amount to a noisy, expensive eyesore that would represent nothing more than a symbolic commitment to an ideal.

Now, I feel the same way about large-scale wind.

We are asked -- expected, really -- to take it on faith that the environmental benefit of wind energy is worth the cost. The problem is, wind power won't deliver what is promised.

Electricity is produced from a variety of sources in this country, but oil simply isn't a significant supplier to our electrical mix, accounting for less than 2 1/2 percent of U.S. generation -- and even this small fraction is unlikely to be impacted by wind plant development.

Beyond this, those who think that we face a choice between turbines and smokestacks or nuclear plants are kidding themselves. The erratic nature of the wind means that turbines simply cannot supply the base load that other forms of generation do. Those other generators will continue to be needed to back up the wildly variable output of wind turbines, with the probability that in so doing these plants will actually emit more pollution for each kilowatt-hour they generate than if they were allowed to operate normally.

In Denmark the vast majority of their wind-generated electricity has to be exported to neighboring countries at a deep discount, and they are then forced to re-import expensive nuclear power. This has led in part to that country having among the highest electric rates in Europe, and Danish carbon dioxide emissions continue to rise. In Germany, wind plants are widely regretted for the brutal destruction they have inflicted where they have come to dominate the landscape.

What is worse, giant wind plants produce very little electricity. The Hoosac Wind project proposed for the towns of Monroe and Florida, with 20 turbines -- each 340 feet high -- spread out over 1,500 acres and miles of ridge on two mountains, might optimistically produce 14/100 of 1 percent of the electricity used in Massachusetts annually. A hundred and twenty such turbines spiking our ridges would likely produce less than one percent of the electricity used in the state, while that electrical use is going up by around 2 percent -- more than twice as much -- every year. Even if we were to construct new wind towers as fast as we possibly could -- in the process transforming western Massachusetts into a science-fiction landscape bristling with enormous black-bladed turbines, lit day and night with flashing strobes -- we wouldn't even begin to keep up.

The wind industry assures us that wind power will help prevent global warming by reducing carbon dioxide produced by other forms of electric generation. Enxco, the company backing Hoosac Wind, has offered improbably optimistic projections of how much carbon dioxide emission might be avoided by the operation of the plant.

But even if we take their figures at face value, they amount to a mere 23/100ths of 1 percent of that fraction of carbon dioxide that results from electricity generation in Massachusetts, or about 8/10,000ths of 1 percent of US anthropogenic (human-caused) greenhouse gas emissions. In this country, greenhouse gas emissions resulting from electrical generation are outweighed by other man-made sources 2-to-1, while anthropogenic emissions as a whole account for about 3 percent of the world total; the remaining 97 percent comes from natural sources such as oceans and bogs.

In a nutshell: Hoosac Wind's potential contribution to reducing

greenhouse gas emissions, when taken in a broader context, is almost incalculably small.

Unfortunately, for some people the inconvenient truths about wind energy will be too uncomfortable to contemplate. "It's the vision, not the view," they'll say, insisting that the turbines have a symbolic value that trumps their negative impacts on wildlife, on rural economies, and on the quality of life of residents forced to live with them. Wind plant proponents know that having secured the hearts of much of the public in this way, reasoned opposition to their plans to industrialize vast swaths of rural America can be marginalized – and they are spending enormous amounts of money to do just that.

The real reason that multinational entities are intent on constructing wind towers is the combination of generous tax credits and depreciation allowances that are provided for these developments. Huge corporations like Enxco parent EDF – the French energy conglomerate that is the largest operator of nuclear reactors in the world, as well as Europe's leading trader of coal, gas, and oil – consequently form unlikely alliances with organizations that have historically championed preservation. The beauty and ecological integrity of our few remaining wild places is thus sacrificed to a green idealism.

To see the future of the wind debate in America, it's instructive to look overseas. In the United Kingdom, central government policies promoting wind development have sparked a wave of outrage and opposition in rural areas targeted for massive wind plants.

Prime Minister Tony Blair has lent his support to opponents of one wind power proposal among his home constituency, while his government has issued policy that hobbles the ability of other communities to reject wind plants. His attitude mirrors our own Governor Mitt Romney's hypocritical opposition to wind power, which apparently applies only to Nantucket Sound. Meanwhile, the director appointed by the governor to the state's highest environmental authority has stated that her decision not to require an environmental impact report for Hoosac Wind "will set the tone for further development of wind power" in inland Massachusetts.

It appears the scenario in Britain is poised to repeat itself here. Rural communities – from the Gaspé Peninsula in Québec straight down the Appalachian range to the Allegheny Front -- are destined for thousands of turbines if current plans materialize, and Franklin County is in the center of the crosshairs, with the construction of the largest wind plant in New England possibly beginning here next year. While developers offer glib assurances that their projects are beneficial, those questioning these facilities believe that the issues surrounding renewable energy deserve critical and substantive debate, not sloganeering.

[Editor's note: Mr. Roberson has informed me that the promotion of industrial wind power in Massachusetts includes a push for the creation of more municipal utilities, which are conveniently exempt from local zoning restrictions.]

Wind Power Facts

***The most frequently unknown or misunderstood facts
about industrial wind power***

SIZE | FOOTPRINT | OIL | COAL

How big are the towers?

Industrial wind turbines are not the benign little structures you might see in a schoolyard or behind someone's house.

The widespread GE 1.5-megawatt model, for example, consists of 116-ft blades atop a 212-ft tower for a total height of 328 feet. The blades sweep an area just under an acre. The 1.8-megawatt Vestas V90 from Denmark is also common. Its 148-ft blades (sweeping more than 1.5 acres) are on a 262-ft tower, totaling 410 feet. Also gaining use in the U.S. is the 2-megawatt Gamesa G87 from Spain, which sports 143-ft blades (just under 1.5 acres) on a 256-ft tower, totaling 399 feet.

Many existing models and new ones now coming out reach well over 400 feet high, with higher towers and extra-long blades designed to turn the generator in less-than-ideal sites.

The base of the steel tower is anchored in a platform of more than a thousand tons of cement and steel rebar, 30 to 50 feet across and anywhere from 6 to 30 feet deep. Pylons may be driven down farther to help anchor the platform.

The gearbox – which transforms the slow turning of the blades to a faster rotor speed – and the generator are massive pieces of machinery housed in a bus-sized container, called the nacelle, at the top of the tower. The blades are attached to the rotor hub at one end of the nacelle. Some nacelles include a helicopter landing pad.

On the GE 1.5-megawatt model, the nacelle alone weighs more than 56 tons, the blade assembly weighs more than 36 tons, and the tower itself weighs about 71 tons, for a total weight of 164 tons. The corresponding weights for the Vestas V90 are 75, 40, and 152, total 267 tons, and for the Gamesa G87 72, 42, and 220, total 334 tons.

Besides the noise and vibrations such huge moving machines

unavoidably generate, they must be topped with flashing lights day and night to increase their visibility.

SIZE | FOOTPRINT | OIL | COAL

So the footprint is less than 50 feet?

Hardly. First of all, new roads have to be built, or existing ones need to be extensively "upgraded." It requires more than an old dirt logging track to get a 150-ft blade, a 70-ton nacelle, or the huge crane needed to put it all together up a mountain. The road needs to be wide, straight, and very strong.

Several acres around each turbine have to be cleared as well. For best performance, the GE 1.5-megawatt turbine needs 82 unobstructed acres around it and the Vestas V90 needs 111. On a ridgeline, the sloping away of the land and the hope that the wind is always perpendicular to the line of the ridge mean that about 5 acres are actually cleared around each turbine.

Access to the area around the turbines must be strictly limited because of physical danger.

A facility may also require a new substation or two, as well as new transmission lines.

The combination of all this -- road building, extensive clearing, and the installed facility itself -- not only significantly degrades and fragments wildlife habitat but also has a serious effect on erosion and water flow, not to mention the aesthetics of a mountainside or open land.

And of course the visual intrusion affects the landscape for miles around.

SIZE | FOOTPRINT | OIL | COAL

Still, we need to reduce our dependence on foreign oil.

Wind turbines produce electricity, not gasoline or heating oil. In the U.S., oil (mostly in the form of the otherwise unusable sludge left by gasoline refinement) is used to produce less than 2.5% of our electricity. We export more than twice that amount. Our electricity has nothing to do with our dependence on oil, either domestic or foreign.

SIZE | FOOTPRINT | OIL | COAL

We need to reduce our use of coal, then, or nuclear.

Burning coal provides more than half, atomic fission more than a fifth, and burning natural gas about a sixth of our electricity. All of these have serious environmental and geopolitical shortcomings that we do indeed need to reduce.

Unfortunately, wind turbines can't replace them – or even reduce their use or slow their growth.

Because of the way the electric grid works, constantly matching supply with demand to avoid dips and surges of power, the variable production of wind turbines is treated as part of the demand side of the equation. A base level of power is provided from large plants, and other plants are kept burning to be able to provide the maximum likely power (peak load) needed as it varies through the day. As demand drops, those plants are diverted from power generation, and as demand rises they are brought back on to resume generating the needed power. These plants burn fuel whether or not they are producing electricity.

In other words, these peak load plants must continue burning fuel when demand falls or wind production rises, because either trend may reverse at any time. Because they are out of the control of the grid's dispatchers, just like user demand, the wind turbines' only effect is to bring the spinning standby plants in and out of production. But, again, the plants continue to burn their fuel. And the additional fluctuations of wind power add to the cost and inefficiency of that burning.

A further irony is that because an increase in wind power capacity is seen on the grid as an increase in demand fluctuation, it requires dedication of other grid capacity to cover it. Rather than reduce, then, wind power may actually increase the use of other fuels.

campaign against the proliferation of wind turbines.....
Theresa May said depending on size, a turbine would have to be built at least every other day if the Government is to meet a target of ten per cent of renewable energy by 2010. She said: "I think it is staggering that the Government is out to meet this target but does not appear to have a strategy to do so. It makes me question what their real commitment to renewable energy is."
Reports from Europe this weekend indicate that countries such as Germany and Denmark - often held up as publicly popular success stories by the British wind industry - are now feeling the anger of voters at the low frequency humming, stroboscopic effects of blades in the

Need Title

UK articles

March 27 2004 ~ "...a world market worth hundreds of millions of dollars"

Herald Sun (Australia) "A GLOBAL manufacturing plant for wind energy components will be built in Victoria, creating up to 300 jobs and millions of dollars in exports. German energy giant RE Power will join forces with three Victorian companies to establish the plant, under a deal brokered by Energy Industries and Resources Minister Theo Theophanous. Under the agreement, wind-turbine blades and towers would be manufactured and assembled in Victoria for a world market worth hundreds of millions of dollars."

March 9 ~ WIND TURBINE NOISE PROBLEMS

Letter in New Zealand's Scoop.co.nz "Wind power advocates' cavalier dismissal of two British studies indicating health problems arising from low frequency noise produced by wind turbines offers no evidence to back their claims.

New Zealand company Windflow's noise-plagued two-bladed turbine and hollow tower (most modern turbines use three blades and a lattice construction tower) appears to put "revolutionary" design ahead of practical considerations. Meanwhile, Green party leader Jeanette Fitzsimons' claim that "people didn't tend to choose to live" in high wind situations ignores the plight previously brought to her attention of the Banks Peninsula community who have had to live with Windflow's turbine noise which is considered unacceptable up to **three kilometres away** even out of direct line of sight. (Windflow's own website says most modern turbines are inaudible at three hundred metres). Perhaps the Green party's financial investment in Windflow is clouding Ms Fitzsimons' judgment?

A recent New Scientist article stated, "Two-blade rotors suffer harmonic problems, dangerous vibrations at certain resonant speeds Three-bladed rotors are the ideal choice. They are well-balanced, aesthetically pleasing and offer a high enough speed of rotation".

If Windflow can't get it right on the audible noise levels and dismiss out-of-hand the effects of low-frequency (inaudible) noise it would seem that producing a "revolutionary" design is taking precedence over all else - not a good move for a supposed leader in wind energy technology."

March 5 ~ How many definitions of the word 'eliminate' are there?

WMN DTI statement said: "The WMN article picked up on the word 'eliminate' out of context. The Renewables Innovation Review simply acknowledges that there are currently a number of barriers to the development of renewable energy in the UK including: improving the planning environment for renewable energy developments and addressing public opposition. Addressing these barriers will increase the expansion of renewables in the UK...." ...But WMN Editor Barrie Williams defended the story. He said: "How many definitions of the

word 'eliminate' are there? This was not taken out of context. It quoted the report entirely accurately."

March 4 2004 ~ INQUIRY VISITS SITE OF TURBINE PROPOSAL

WMN "The debate over a proposal to build three wind turbines in North Devon took to the fields around Torrington yesterday. The planning inquiry into arable farmers Perry and Sara George's proposal to site three wind turbines on land at their farm at Higher Darracott, near Torrington, held its site visit.

... As well as the experts who have been putting the case for and against the proposal, the site visit was open to other people with an interest in the public inquiry.

A number of protestors turned out, some with placards. Others spray painted the word "No" in large white letters on the road outside the field where the turbines would be built. Yesterday's visit was marked by heavy rain, but despite this the whole group trudged across Mr and Mrs George's fields to examine at first hand the views and also the exact spots where it is proposed the turbines should go.

Drenched, but unbowed, Mr Cullingford listened with patience to the points made to him by all those involved and promised to return when the weather improved and visibility was better. Today, the inquiry returns to Langtree village hall where individuals will be able to put their points."

March 3 ~ RSPB position on wind power and other renewables

Read in full "...the RSPB favours a broad mix of renewables, especially those, like solar energy, with large long-term potential and minimal environmental impacts. However, for the foreseeable future, wind power – the most advanced and widely available of the new renewable technologies – has the greatest potential to make a significant difference in the UK and globally, at an economic cost increasingly close to that of fossil fuels.

The RSPB therefore supports the increased use of wind power, as long as wind farms are sited, designed and managed so they do not harm birds or their habitats. The development of any form of energy, renewable or otherwise, must not compromise nature conservation objectives."

March 3 ~ Birdsong throws wind-farm plans into chaos

Guardian " Government plans to switch Britain to renewable energy were faced with turmoil last night when the RSPB, the bird protection charity, threatened legal action to halt some schemes.

Virtually all the sites licensed for the second round of offshore wind farms are in areas identified as of potential international importance for birds, the RSPB warned.

The government is banking on wind power to deliver its promises to meet Kyoto treaty targets and wants 10% of all electricity to come from

alternative energy sources. But it has already been warned that opposition from the Ministry of Defence, which wants to halve all wind-farm proposals because of fears they interfere with radar, is causing chaos. The RSPB says there could be many more wind farms which will be vulnerable to a legal challenge because of new regulations drawn up by the European commission.

A directive requires member states to draw up lists of all the special protection areas (SPAs) where birds are free from outside interference and then give them protection under European law. The UK government has been slow to assess which parts of the British coastline could be ruled out for development, so companies are unclear which new schemes might be vulnerable. ..."

March 3 ~ "This was a television programme that will get right up the nose of Government ministers, developers, energy companies

- in fact, anyone trying to build windfarms around Britain."

The Western Morning News reports on last night's "Bee in your Bonnet" programme on the fight of Ann Metcalfe in the Yorkshire Dales.

"By the end of the programme, Ann, a 58-year-old school teacher, was giving a passionate speech to local councillors, producing leaflets any public relations firm would be proud of and addressing a media pack with botanist David Bellamy at her side. The programme did stress that not everyone in the community agreed with them but this was not about whether the Friends of Scout and Knowle Moors were right in their protest. This was about their right to protest..."

March 3 ~ From the Western Morning News

- **PROTESTS ARE GROWING OUT OF FEAR AND CYNICISM: NOEL.**
 "...Shadow Energy Minister Anne McIntosh accused ministers of being "obsessed" with windfarms and urged them to look at other technologies, like combined heat and power (CHP). Miss McIntosh said the cost of connecting windfarms to the national grid would top £2 billion by 2010, if the Government continued with its current plans, and create "hideous and dangerous new pylons across the countryside".
- **WINDFARMS CAN WORK IF OPPOSITION 'ELIMINATED'**
 "The Renewables Innovation Review, conducted by the Department of Trade and Industry and the Carbon Trust.... notes that public opposition was "confirmed" from last year's Energy White Paper consultation. ... Ministers are to spend £2m on an "inspirational" communication campaign to sell renewable energy to the public and to planning authorities. A consultation has also been run on proposed planning changes to ease controls on windfarm development.
- **ELIMINATE THE PROTEST "** A document urging the Government to "eliminate" public opposition to windfarms has been described as "evil propaganda"... (Noel) Edmonds, who lives in Devon, added: "It seems they would rather use confrontation than consensus. This is propaganda

of the most evil kind." And campaigner Alan Nunn, from St Austell, said: "They think they can just bypass public opinion and peoples' love of the landscape."

March 2 ~ "... I have become very determined to see this through. There are so many people behind us and you don't want to let anyone down.

WMN on Ann Metcalf's fight to stop the development of 26 wind turbines, each more than 300ft high on the moors near her home from going ahead.

"She says she has the support of many in her community, the backing of three local councils, an independent environmental consultant - and even TV botanist David Bellamy. "They (United Utilities) talk about creating things in harmony with nature but they are going to build these 327ft monsters. I think we are talking a different language." "We want to get information to people who still think these things are like the windmills in Enid Blyton stories. It is difficult to visualise but they're going to be two thirds the height of the Blackpool Tower. It's tough but I have faith that we will win in the end."..."

March 2 2004 ~ Wind Power: "does not merit continued government promotion or funding" concludes the National Centre for Policy Analysis

NATIONAL CENTER FOR POLICY ANALYSIS - Brief Analysis - No. 467 (February 23, 2004) "Environmentalists have long argued that renewable energy sources (such as wind, solar, and geothermal power, and the burning of biomass), are preferable to fossil fuels (oil, natural gas and coal). Historically, fossil fuels have been relatively abundant and significantly less costly; however, in recent years the price of alternative energies, particularly wind power, has fallen. Under certain conditions, wind power has become cost competitive with conventional fossil fuel energy. In addition, alternative energy advocates claim that burning fossil fuels pollutes the air and emits greenhouse gases that many people argue are causing potentially catastrophic global warming. Renewable energy promoters claim that wind power is cheap, safe and "green." These claims are untrue. ..." [Read full text](#)

or [Download in PDF format](#)

Concludes: "Wind power is expensive, doesn't deliver the environmental benefits it promises and imposes substantial environmental costs.

Accordingly, it does not merit continued government promotion or funding."

Feb 29 2004 ~ Rare duck may scupper plans for giant wind farm

Conservationists and migrant birds line up against developers of offshore turbine

Independent on Sunday

"Britain's largest ever offshore wind farm could be sunk before it is built - by a small but very rare black duck. Naturalists have recently calculated that up to 20,000 common scoter - far more than previously thought - spend the winter on the wind-battered waters of Shell Flats, about 8km off Blackpool, making it the second largest home for the bird in the British Isles.

But two of Britain's largest energy companies, Shell and Scottish Power, and a major Danish developer want to turn Shell Flats into the UK's flagship offshore wind farm. They have applied to build 90 130m-high wind turbines on the site, at a cost of £350m. But, in a legal battle that threatens the Government's plans for a massive expansion of offshore wind farms, conservationists are preparing to take the Government to the European Court of Justice if the project gets the go-ahead. The common scoter is on the UK's "red list" of critically endangered birds Whitehall has badly mishandled the approvals process, in its rush to give wind energy its support. Under European Union law, the Department of Trade and Industry (DTI) is required to carry out detailed "strategic environmental assessments" to ensure marine developments, including oil and gas fields, do not unnecessarily harm sealife. Mark Avery, deputy chief executive of the RSPB, is to raise the charity's concerns at this week's conference, and will warn, "If this project goes ahead, the environmental credentials of offshore wind will be badly damaged. If the Government allows it, it will be breaking European law." ..."

Feb 26 2004 ~ Turbines would pose a threat to Tourism

Western Morning News "Plans to build three 266ft tall wind turbines in North Devon would harm the area's tourist trade, a public inquiry has been told. The inquiry is hearing an appeal against Torrington District Council's refusal to grant planning permission to build the turbines at Higher Darracott, near Torrington.

In support of the district council's stand against the turbine application by local farmers Perry and Sara George, the chief executive of the North Devon Marketing Bureau, Nigel Smith, warned that the turbines would harm existing tourism and threaten its future development. Mr Smith said that about one-quarter of Devon's tourism industry is in the geographical area of North Devon and brings about £255 million to the local economy. He said that specifically in the Torrington district, tourism produced £134 million of expenditure, supported just under 5,000 jobs and accounted for about 18 per cent of employment..."

Feb 25 ~ 266FT Wind Turbines face Public Inquiry

WMN "...The plan is to build three turbines at Higher Darracott near Torrington in North Devon. They would tower above the height of Nelson's Column, which stands at 167ft.

An application by arable farmers Perry and Sara George was turned down by Torrington District Council's plans committee last year and the matter has gone to appeal. Yesterday, a public inquiry into Mr and Mrs

George's appeal against the refusal of planning permission was opened at Langtree Village Hall. The appeal is being supported by West Coast Energy, the firm which backed the successful appeal to build three 246-foot-high wind turbines at Bradworthy, which is also in the Torridge district....In opening the appeal, barrister David Hardy said that Torridge District Council's objection to the proposed wind turbines was "unsustainable" in two senses of the word. He said it was unsustainable environmentally that there were no wind turbines operating to supply electricity to the national grid and it was "evidentially" unsustainable in that nothing the council had put forward justified refusal of planning permission..."

Feb 17 ~ The Royal Town Planning Institute comments on draft Planning Policy Statement 22. (PPS22)

<http://www.rtpi.org.uk/resources/policy-statements/2004/feb/pol20040212.pdf> "..... 6. In terms of the risks arising from following Option 4, the Institute is concerned that the decision to maintain the focus of PPS 22 on the development of renewable energy projects alone may :

- i. weaken the urgency of the message of the need to cut emissions by concerted, cross-cutting programmes of energy substitution and efficiency.
- ii. fail to address public suspicions that large-scale renewable energy projects, particularly wind farms, are meeting the demands of the renewable energy industry at the expense of other environmental and social concerns.
- iii. fail to secure the level of diversity of energy generation and capture that is required by the Energy White Paper.
- iv. fail to adequately encourage and support innovative and communitybased initiatives for energy auditing, management and generation....."

Feb 16 2004 ~ Riley County in Kansas (US) is conducting a poll

"Do you support the development of commercial Wind Energy Conversion Systems (Wind Farms) in Riley County?" Voting seems to be fairly even at the moment.
(The website also has a link to the American Wind Energy Association's persuasive FAQs on wind power(pdf).)

Feb 15 ~ March of the Windfarms is moving with indecent haste

Western Morning News" ...having seen one windfarm in Cornwall, I am totally opposed to any more of these unsuitable monstrosities being erected to satisfy a Kyoto directive which hasn't been thought through properly, and which John Prescott is pushing through with indecent and ill-advised haste.

..... Lincolnshire County Council is taking a tough stand against the latest proposed regional planning documents PPS7 and PPS22, which

can give carte blanche to development of any part of our countryside despite local objections. . . .

.....Wind turbines are not the answer as other countries have found out already to their cost.

They are expensive and unsustainable, cause ill health to those living around them through noise and subliminal vibration, fill valuable agricultural land with concrete which will never be removed, they kill our diminishing bird life especially raptors, cause distorting light flicker over a wide area, interfere with aircraft radar, and will cause increases to our already high electricity bills because of all the extras which will be added on."

✂ Feb 14 2004 ~ "...a great deal of research has shown that onshore wind turbines are a politically driven 'quick-fix' which has not been fully reasoned through."

(The Renewable Energy Debate and Wind Power)

"... They are:

- Ineffective as to overall emission savings.
- Unreliable, inefficient and unpredictable as to power generation, requiring costly and inefficient standby power plants.
- Uneconomic without subsidy.
- Damaging to the greater environment, to tourism, and to the health and safety of local residents....

By concentrating on windpower, research and engineering effort is being diverted from other, less environmentally damaging and more reliable renewable energy sources. For the power companies windpower is a quick, proven and relatively simple route to government subsidies Government has drawn out of a hat the catchy phrase '10% from renewables by 2010, 20% by 2020' without considering whether this is practically achievable, economically feasible or scientifically necessary. Whilst the targets are well-intentioned, they are unrealistic to the point of naivety. They vastly underestimate the capacity of Britain's engineering base to build tens of thousands of wind turbines and connect them to the National Grid, which itself is not designed to receive embedded generation (e.g. wind turbines).. . ." Read in full

Feb 14 ~ Ofgem has attacked government plans to subsidise transmission costs for wind farms

in remote areas as "unnecessary and misguided". The Financial Times says. "The government requires 10 per cent of electricity to be generated from renewable energy sources by 2010. It is concerned that schemes may not be developed if operators in remote regions have to pay high transmission costs."

John Burnett, Lib-Dem MP for Torridge and West Devon is reported in the Western Morning News as saying

".. he could not understand why more windfarms were even being considered when wind turbines were a "failed technology" and there were mounting concerns about their effects on people's

health. "This should be challenged and I will be doing that. I'm surprised that there hasn't been a complete rethink about on-shore windfarms, given the fact that there is so much evidence that, far from reducing fossil fuel use, they increase it - because they only work 30 per cent of the time and have to be fired up by the power stations..." read in full.

Feb 11 ~ WIND TURBINE TALKS START

Doncaster Today "CONSULTATION has started on controversial plans for a wind farm.

Plans to erect 28 80 metre-high wind turbines on the outskirts of Thorne and Moorends were submitted to the government, which will decide on the plan, last month. Now residents have less than four months to respond to the United Utilities' green energy proposal, which has been referred directly to the Department of Trade and Industry...United Utilities claims that the plan - known as the Tween Bridge Project - will generate enough power to serve 14,000 homes. As well as the turbines other buildings, such as control cabins and a visitor centre, are also proposed. Coun John Hoare, Doncaster Council's cabinet member for economic development, said: "This process is quite different to an ordinary planning application, as the council is not the authority that will determine the application. It is up to the DTI or a panel of inspectors to decide if it must go to a public inquiry, to grant permission."

Feb 9 ~ Warning on turbine health threat ignored

From Western Morning News "... Plymouth GP Dr Amanda Harry which highlighted serious health effects on people living near the Bears Down windfarm near Padstow in Cornwall.

Conservative peer Lord Dixon-Smith urged ministers to investigate the study, which showed that 93 per cent of people living close to wind turbines reported that their lives had been "adversely affected", with some moving house to get away from the problem.

Dr Harry said it was clear that low-frequency noise generated by windfarms caused "extreme distress" to some people "Does that not suggest at the very least that the Government should consider a moratorium on further construction until the matter is properly cleared up?" he asked. But Science Minister Lord Sainsbury dismissed the call, saying the health effects of windfarms were considered to be "non-existent at this stage".

The South West has been earmarked for around 250 giant turbines - the equivalent of 1,000 of existing machinery - and fears are growing that the health problems could multiply (Lord Sainsbury) said Denmark's decision to site more windfarms at sea was for efficiency reasons rather than health concerns...."

Feb 7 2004 ~ " these industrial, uneconomic structures that are

already littering the uplands and will soon be covering the lowland countryside as well, unless the government can be persuaded otherwise.."

An emailer writes, "I have recently become interested in wind farm issues - there is a proposal to put up six 100-m turbines on a disused airfield that is surrounded by some of the prettiest and most unspoilt countryside in Suffolk. This week's Country Life (5.2.04) contains an excellent editorial entitled JOLLY AWFUL GREEN GIANTS. It is based on the proposal at Parham which is concerning us so much - but it covers most of the concerns we all have about these industrial, uneconomic structures that are already littering the uplands and will soon be covering the lowland countryside as well, unless the government can be persuaded otherwise.

As you probably already know, there are many windfarm websites - two of the best are the country guardian one and also www.wind-farm.org."

Feb 3 2004 ~ James Lovelock has told the Western Morning News that he now regrets his endorsement of windfarms in the Westcountry

James Lovelock, revered by many for his Gaia theory as well as for being an independent scientist of great stature and a genuine and delightful man

"believes we face devastating consequences from climate change and that putting up a few wind turbines will not address the problem. Dr Lovelock cannot emphasise enough how anxious he feels that time is running out to address the issue of climate change. "Windfarms won't cut it at all," he said..."

Read in full.....

Jan 25 2004~ Wind farms 'make people sick who live up to a mile away'

Telegraph "Onshore wind farms are a health hazard to people living near them because of the low- frequency noise that they emit, according to new medical studies. Doctors say that the turbines - some of which are taller than Big Ben - can cause headaches and depression among residents living up to a mile away.

One survey found that all but one of 14 people living near the Bears Down wind farm at Padstow, Cornwall, where 16 turbines were put up two years ago, had experienced increased numbers of headaches, and 10 said that they had problems sleeping and suffered from anxiety.

..... "There is a public perception that wind power is 'green' and has no detrimental effect on the environment," said Dr Osborne. "However, these turbines make low-frequency noises that can be as damaging as high-frequency noises.

..... In Denmark, where wind turbines were introduced as long as 30 years ago, the government has responded to public demand and stopped erecting onshore turbines because of the noise hazard. Dr Stephen

Briggs, an archaeologist who lives in the village of Llangwryfron in West Wales, initially welcomed the news that 20 turbines were to be built in the hills behind his home. He said: "I'm as green as the next man and the developers assured us that the windmills would cause hardly any disturbance, but once they began operating I couldn't work in my garden any more - the noise was unbearable. It was as if someone was mixing cement in the sky." ..."

Jan 21 2003 ~ Second U-Turn on Wind Power

WMN "Plans to build a wind turbine in North Devon have been dramatically halted just days after another application appeal was scrapped.

Last week, National Wind Power (NWP) announced it had decided to withdraw its appeal against the rejection of an application to build three 300ft-high turbines at Higher Bockett, Ashwater, near Holsworthy. Now the company has dropped another appeal against the rejection of an application to build a single turbine, 300ft tall, at Cam Brac on the outskirts of Pyworthy, near Holsworthy....A series in the WMN has highlighted concerns about onshore wind turbines, and their potential effects on the environment, health and tourism. "

Jan 15 ~"The reason we have tended to go in the direction of wind power is the subsidy..."

WMN "Science Minister Lord Sainsbury has told peers that the Government's target for a massive expansion of renewable energy will be driven mainly by new windfarms, despite calls for greater investment in tidal power.

Lord Sainsbury's comments came in response to calls from peers to provide greater investment for tidal power.

Lib-Dem peer Lord Hooson said that using the tidal power of the River Severn alone could provide up to 10 per cent of the nation's energy needs. Lord Hooson said the development of turbine technology had moved on enormously since the last assessment of the Severn barrage project and urged ministers to "look anew" at the feasibility of the massive scheme.

Lord Hooson also questioned the Government's reliance on wind power, saying that ministers "should give greater priority to harnessing tidal power, rather than wind power".

He also questioned the "reliability" of wind power, adding: "The reason we have tended to go in the direction of wind power is the subsidy.Are the Government satisfied with the reliability, viability and cost of that being the prime renewable source? Where does the money come from? Is it all European Union money? If so, has any attempt been made to make sure that such subsidies would also be available for research into the development of tidal projects?""

Jan 15 2004 ~ More Reasons needed for turbine plan

Western Morning News "Anti-windfarm campaigners are calling on National Wind Power (NWP) to make a full explanation of why it has decided to no longer support a plan to build three wind turbines in North Devon. Earlier this week the campaigners greeted with jubilation the news that NWP had announced it had decided to withdraw its application to build three 300ft-high turbines at Higher Beckett, Ashwater, near Holsworthy. But the campaigners said the reason for the withdrawal offered by NWP was inadequate. "Obviously we are extremely pleased, but we do wonder if NWP are going to tell us exactly why they withdrew," he said. "What does concern people in the area is if NWP have backed out now, but might come back later. We want to know why they made their decision.

Dec 2 2003 - "Inspirational Communication" a new phrase for propaganda?

The Western Morning News under the headline "Huge Increase in Windfarms" "...Energy Minister Stephen Timms yesterday paved the way for a huge increase in the number of windfarms as he told the industry to "go out there and build"....The move is designed to encourage billions of pounds of investment by the private sector in windfarms and other forms of renewable energy. Among projects that could be accelerated is the first windfarm in Devon.

It puts ministers on a collision course with the growing band of campaigners in the Westcountry and beyond who believe windfarms cause unacceptable damage to the landscape while providing questionable benefits....The Government yesterday acknowledged the growing opposition with the announcement of £2 million funding for an "inspirational communication" campaign to sell renewable energy to the public and planning authorities, who have thwarted many windfarm plans in the South West.

South West Euro MP Giles Chichester was "astonished" by the Government's decision to increase its support and targets for the renewable sector.

Mr Chichester, Conservative energy spokesman in the European Parliament, said: "Their policy is wholly unrealistic. We would need thousands and thousands of wind turbines to meet the existing target; I am astonished that they have increased it. Even if you built them you would have to provide back-up for times when the wind is not blowing or blowing too strongly. "Ministers are just following fashion. I am fully behind those who are resisting these masts in most of Devon because there are fundamental problems with the technology yet they would severely scar the landscape."

April 4 2003 ~"Terror of being thought pro-rich or anti-growth has neutered the supposed defenders of the countryside."

"..... The greens take money for wind turbines. Local lobbies concede planning permissions for "key-worker housing". Nobody dares defend rural beauty for its own sake. All take refuge in such weasel words as

sustainable, affordable and holistic, code for "we surrender". .." Simon Jenkins in the Times

March 7 ~ "Counties matter, because the Government is about to abolish them"

Simon Jenkins (external link) today..."...Upland England will one day be the only place safe from the Government's nightmare vision of shed parks and executive estates. The most tolerable parts will be the inland combes of Dorset and the secret dales round Bradford in Wiltshire. It will be the lost villages of the Berkshire Downs and the hidden glades of Chiltern Buckinghamshire, where the Blairs' Chequers will keep the wind turbines at bay....."

Windmills fan the flames of unrest

Booker's Notebook • Sunday Telegraph - March 2 2003

Councillor Gerald Sewell of Aspatria, near Wigton in Cumbria, has supported the Labour Party for 40 years. But he has protested to Tony Blair about the way a planning application for an eight-turbine wind farm at the beauty spot of Wharrels Hill, between the Lake District and the sea, was railroaded through by a Government planning inspector. This go-ahead was despite objections from every council in the area and bodies from the Lake District National Park Authority to the Council for National Parks.

Several fellow councillors resigned from the party after the inspector swept aside all normal planning rules, arguing that the Government's support for renewable energy must outweigh all else. Such outrage is likely to become commonplace following last week's pledge in the energy White Paper issued by the Department for Trade and Industry that normal planning rules are to be relaxed still further to ensure that the Government meets its European Union obligation to produce 10 per cent of our energy needs from renewable sources by 2010.

The White Paper has drawn fire from energy experts for its failure to propose any effective response to the impending crisis as, within 10 years, Britain will lose much of its home-grown energy from gas, coal and nuclear power. Prof Ian Fells, of Newcastle University, describes the failure to plan for renewing our nuclear power capacity as "reckless". Without nuclear energy, we shall become dependent on gas, oil and coal imported from north Africa and other countries whose stability cannot be guaranteed. But the most frightening part of the paper is the section that, with a startling absence of facts or figures, endorses our EU obligation to spend billions of pounds on wind power.

To reach this target, Prof Fells points out, we would have to build 20 two-megawatt turbines every week until 2010. Most are much smaller than this, so we may need some 20,000 wind generators, up to 400 ft high (we have only 1,000), dominating thousands of square miles of countryside. All this to produce electricity nearly twice as expensive as that generated from gas, oil or even nuclear power (official sources show

that coal- or gas-generated power costs £16 per MW hour, nuclear power £19 and wind power £28.80).

The problem with wind power is not just that it is ludicrously uneconomic, yielding nothing like the environmental benefits its supporters claim, but that it is so inefficient. What its proponents never explain is that the average turbine produces only 25 per cent of its theoretical capacity. To guarantee continuous supply, 100 per cent of its capacity has to be duplicated by more conventional forms of power generation. For all the 20,000 turbines the Government wants, we will still have to invest in other power sources.

The reasons we have wind power are, first, the EU's "renewables obligation", which compels generating companies to buy power from wind farms; and, second, the EU's "climate change levy", which penalises industry for not using it. This huge hidden subsidy has turned wind power into a bonanza for companies such as National Wind Power to produce a mere 0.3 per cent of our energy needs. A single aluminium works in Anglesey uses 220 MW, more than is produced by every turbine in the country.

Wind power is one of the great self-deceiving fantasies of our age. Mr Blair, who writes the foreword to the White Paper, may have fallen for the make-believe but it threatens to become a central ingredient in our forthcoming energy disaster. It is not surprising that people like Councillor Sewell are so angry. 25 February 2003: Energy policy puts climate before consumers ([external link](#))

The German experience

...See <http://mitglied.lycos.de/WilfriedHfeck/resol.htm> "...Under the pretence of an ecologically and economically sensible energy policy the exploitation of wind energy in the Federal Republic of Germany is being advanced by the installation of thousands of wind turbines - primarily on the coast, but now increasingly also in the interior of the country. Yet the arguments given in support of this do not in the least bear critical reflection! In reality, it is a matter of the wind industry pushing commercial interests through, to the detriment of the general public. Throughout Germany, citizens immediately suffering from the harassments from wind turbines as well as opponents of the industrial deformation of our natural regions have integrated into over three hundred citizens' action committees and action groups to stop this disastrous development. Behind the subscribers to the resolution there is a steadily growing army of opponents of the exploitation of wind energy through wind turbines. From the numerous reports in the media it can be inferred that the acceptance of the exploitation of wind energy is constantly decreasing among the population..."

Feb 27 ~ "We are tending to concentrate on wind rather than wave, water, energy crops and bio-gas. People don't want wind farms."

Telegraph on Tuesday Richard Saville (external link): "...councillors bowed to local opposition and rejected the plans.....David Pinney, Torrington council's director of planning and technical services, said: "There were two concerns in all three cases. One was the visual impact both from a distance and close up. We are talking about very big structures in a rolling landscape. "The second was the noise from the swish of the rotor blades." He added: "People were genuinely concerned. The message from this is that we need to be more diverse in the way we look at sustainable energy. "We are tending to concentrate on wind rather than wave, water, energy crops and bio-gas. People don't want wind farms....."

Feb 25/26 ~ WIND WARNING

From Western Morning News (external link) - 25 February 2003
 "The treasured Cornish landscape must not be sacrificed to "monster" wind turbines - some the height of Truro Cathedral - to meet the Government's renewable energy targets, campaigners have warned. Trade and Industry Secretary Patricia Hewitt yesterday unveiled a strategy to cut carbon dioxide emissions through a major expansion of renewable power sources. But it met with a chorus of concern from conservationists as well as environmentalists and industry...."
 See also what Christopher Booker in the Sunday Telegraph had to say last year about wind turbines:

Extract "So ludicrously expensive and inefficient is this form of power generation that Denmark, the world leader, which produces 13 per cent of its electricity from wind power, has just called a halt to the programme which has given it the most expensive electricity in Europe, and yielded no reduction in the emission of "greenhouse gases".

Yet at this very moment Mr Blair's advisers in his Policy and Innovation Unit call for an expansion in wind generation which, in order for Britain to equal Denmark's current level of 13 per cent, would require at least 20,000 new turbines, in addition to the 900 we have already.

To see how absurd this is, one has only to consider the proposal to erect 165 two-megawatt turbines over 48 square miles of the Cambrian Mountains in mid-Wales. Each will be around 400 feet high, the size of Salisbury Cathedral or Millbank Tower. Because they cannot operate when winds are either too weak or too strong, they produce only a quarter of their capacity, requiring permanent backup from conventional power stations. Total output will be about enough to provide power for a large village, yet each turbine will require a subsidy of £100,000 a year, and any carbon dioxide emissions it saves will be made up by that emitted from just four container lorries...."

(more)

Feb 25/26 ~ "... the Government should be "pushing" less damaging alternatives like wave energy and energy crops"

Western Morning News

New Energy Vision by Andy Greenwood ([external link](#))

"...Of major concern to conservationists yesterday was the potential proliferation of intrusive wind turbines across the Westcountry skyline. They fear that as the most high profile and readily available alternative to conventional sources, it will lead to a rash of applications as the Government increases its "green energy" targets. Geoffrey Swarder, of the Council for the Protection of Rural England in the South West, said the Government should be "pushing" less damaging alternatives like wave energy and energy crops...."

See also the CJA's press release "Don't forget the farmed fuels"

Feb 25/26 ~ real fears were aired in the Westcountry last night that the move could "steam-roller" through windfarm applications despite local opposition.

Western Morning News ([external link](#)) extract: "South West Tory MEP Dr Caroline Jackson, chairman of the EU's environment committee, said recent plans for windfarms in Devon had been rejected because of local protests. "This could lead to the Government over-riding local opposition to windfarms," she said. "If the Government decides that local people will not have as much opportunity to object, then I think that's bad law, bad government and a dictatorial approach more relevant to North Korea than North Devon."..."

"Wind companies steadfastly maintain that there is no problem with ice throw. A 2003 study concluded that New York has the iciest conditions in the entire country. But developers in New York State routinely ignore evidence that ice can be thrown over 1600 feet by placing turbines less than 500 feet from roadways."

— from Remarks Delivered To The Assembly Committee On Energy And The Subcommittee On Renewable Energy, Examining Policy And Implementation Plans For The RPS Program March 7, 2006 by an Ad Hoc Coalition Of Local Community Groups In Upstate New York. [Click here for full transcript.](#)

Clinical Study of "Wind Turbine Noise Syndrome"

Nina Pierpont, MD, PhD
March 4, 2006

Nina Pierpont, MD, PhD, Fellow of the American Academy of Pediatrics; former clinical professor of pediatrics at the College of Physicians and Surgeons Columbia University, New York, New York, has begun a clinical study of turbine noise syndrome."

National Academy of Medicine in France warns of wind turbine noise effects

Dr. Pierpont is asking anyone living near wind turbines and suffering ill effects of whatever sort which he/she suspects are a result of the wind turb contact her at either (518) 483-6481 (Malone, New York, USA) or pierpont@westelcom.com (www.ninapierpont.com). She will do a telepho interview (takes about 30 minutes), where your identity will be held strict confidential. What she is after is evidence and data (as with any medical re project, your identity would remain confidential. always and forever).

Dr. Pierpont's study will be published in a leading clinical medical journal sometime within the next 12 months, she expects. One of the purposes of t is to influence public policy, around the world, to ensure the proper, medic responsible siting of wind turbines.

A summary of Dr. Pierpont's credentials is here.

Documents preceded by  require Adobe Acrobat or Acrobat Reader to view. If you do Acrobat, you can get a free copy here.

- **Professor Terry Matilsky On Ice Throw:** Dr. Terry Matilsky, As: Professor of Physics and Astronomy at Rutgers University, address kinetics of ice throw..."The bottom line is that ice, debris or anything breaking off the wind turbines blades (including the blades themselves) impact a point almost 1700 feet away from the base of the turbine..."
- **RISK ANALYSIS OF ICE THROW FROM WIND TURBINES:** presented at BOREAS 6, 9 to 11 April 2003, Pyhä, Finland. Here Annette Westerhellweg, Jürgen Kröning, et al..."Wind turbines are erected far away from houses, industry, etc., as the wind conditions favourable in the vicinity of large obstacles... However, the turbines erected close to roads or agricultural infrastructure in order to avoid expensive access roads for erection and maintenance. This induces a persons passing by the wind turbines, cars passing the streets if ice fall down from a turbine. Especially in the mountainous sites or in the northern areas icing may occur frequently and any exposed structure wind turbines - will be covered by ice under special meteorological conditions. This is also true if today's Multi Megawatt turbines with from ground to the top rotor blade tip of more than 150 m can easily lower clouds with supercooled rain in the cold season, causing icing the leading edge."...

"...(page 2) If a wind turbine operates in icing conditions which are in [1], two types of risks may occur if the rotor blades collect ice. If fragments from the rotor are thrown off from the operating turbine d

aerodynamic and centrifugal forces or they fall down from the turbine is shut down or idling without power production..."

"...(page 5) In principle, a shut down wind turbine does not differ from structures like towers, antenna masts, masts of power lines, etc. concerning ice accretion. Depending on the rotor position of the braked or idling turbine, different fall widths along the prevailing wind will result at the end of an icing event and increasing temperatures. For automatically detecting the rotor blades, several methods can be recommended. However, at all these methods or instruments have to be improved and further validated. Observation showed that ice fragments which fall from a stopped rotor into smaller parts on the way down to the ground. In the worst case, large fragments reach longer distances from the still standing rotor - two long fragments have been investigated."...

"...Conclusion: The experience and the results of many calculations during operation show that small fragments are hitting the ground in a larger area than those with a big area whereas from stopped turbines the larger fragments can be transported wider than small ones. However, provided that the turbine is operating the area of risk is larger than at standstill. In both cases the wind direction is an important parameter for the assessment of possible risk. It is an important parameter for the control systems concerning its behaviour during icing events. Ice sensors and also ice detection by using power curve comparison or two anemometers - one heated, one unheated - is not reliable enough at the moment and needs to be improved. There is still a lot of information required from operators after icing events in their wind farms. Observation of the turbines and especially the blades by web cameras can be a suited, but time consuming method in the Tauernwind project. Calculation methods as well as the assumptions made for the ice fragment fall have to be improved and validated against observation, if available."

"...As a general recommendation it can be stated that wind farm developers should be very careful at ice endangered sites in the planning phase. Ice should be taken into account as a safety issue. Each incident or accident with ice throw is an unnecessary event and will decrease the public acceptance of wind energy."

- **Man Dies In Wind Tower Fire:** Associated Press, Nov 11, 2005... "A Dakota man died and two people were injured Friday in a wind tower fire in southwestern Minnesota. Benjamin James Thoyson, 26, of Sioux Falls died at the scene. He fell about 210 feet. Deputy Randy Donahue said the other two were able to climb down and escape, but were taken to a hospital."

When help arrived, Donahue said, "the wind generator was engulfed in flames."

- **Why do wind turbines confuse military radar?:** March 4, 2004, by Adam, The Guardian... "The rotating turbine blades fool techniques used by radar to track aircraft."

filter out tall buildings, trees and other stationary objects. And because different blades can be picked out during different radar sweeps, the turbines appear as a confusing, twinkling mass on screens that can be genuine targets difficult to pick out... There are even concerns that they cast a radar shadow behind them, within which enemy planes would be invisible, though recent measurements indicate that it would last for few hundred metres and would hide only very small objects."

- **Windfarm plan hits turbulence:** May 2002, The Scotsman... "Plan for Europe's largest windfarm on a moor south of Glasgow threatens the thousands of airline passengers flying in to the city's airport, according to a senior air traffic controller at Glasgow Airport said: 'If the windfarm goes ahead we will have a disaster waiting to happen. It is an air traffic controller's nightmare when a snowstorm of blips shows up on a radar screen.'

HEALTH

- **Vibroacoustic disease and wind turbines** Saturday, April 01, 2006
Calvin Luther Martin, Malone, N.Y.:

"Mariana Alves-Pereira, Dept. of Environmental Sciences & Engineering, New University of Lisbon, Caparica, Portugal, has for many years led a team of physicians and scientists studying the pathophysiology of low-frequency noise and infrasound on humans. She is Assistant Coordinator of the Vibroacoustic Disease Project.

Alves-Pereira and colleagues have been doing epidemiologic studies on airline pilots and technicians and other people who are chronically exposed to low-frequency noise and infrasound. The effects are grim: cardiovascular, respiratory, neurologic, and renal pathology and symptoms, which constitute vibroacoustic disease.

Alves-Pereira, in discussion with physicians Amanda Harry in the U.S. and Nina Pierpont in the U.S., is now looking into the low-frequency noise and infrasound produced by industrial wind turbines, to determine whether they, too, can cause such vibroacoustic disease (VAD). Alves-Pereira's initial assessment, based on noise measurements taken inside and outside the homes of wind turbine neighbors, is that turbines are indeed a likely cause of

it was Alves-Pereira's initial research, published in numerous scientific journals, which prompted the French National Academy of Medicine in this month (March 2006), to call on the French government to stop wind turbine construction within 1.5 km of people's homes. You should understand that VAD is well established in the clinical literature; it is not conjecture. It has been amply documented and is readily detected by a variety of diagnostic tests.

The question remains: Do wind turbines also produce VAD in people nearby? Again, France's National Academy of Medicine was sufficiently persuaded by the evidence that it called for an immediate minimum (approx. 1 mile) setback of all pending and future industrial windmill residences. In conversations with Drs. Pierpont and Harry, Alves-Pe indicates that she is very concerned about the possible role of turbine source of VAD."

- **Flicker Induced Health Risks: Chatauqua County Citizens For Re Wind...** "There are two distinct types of flicker associated with wind. Shadow flicker arises as the shadow of the moving turbine blades moves across the ground. This type of flicker is most common when the sun is at a low angle in the sky, such as mornings and evenings in the summer and about any time in the winter. These shadows can extend great distances from the base of the turbine, particularly when the shadow is downhill from the turbines... The second type of flicker that can arise from wind turbines is strobing. Strobing occurs when turbine blades catch the sun and reflect it back towards the viewer. Since a turbine blade will be in the position to reflect the sun this reflection takes place up to 60 times per minute (20RPM X 3 blades). The effect is like a strobe light. Strobing can occur at any time of day and can happen anywhere the turbines can be seen - especially from the south and west.

The most severe, though by no means the only health risk associated with shadow flicker and strobing is seizure. It is a known fact that flicker or strobing light can cause seizure in susceptible individuals. Other risks associated with flicker and strobing include headache, loss of balance, nausea and disorientation. Having a seizure is a severe medical issue but if that or for that matter disorientation, were to take place while a person was driving a car or operating farm equipment, it could be devastating to the individual and family."

- **Turbines a Health Risk, Warns Foster Doctor** The Star, March 1, 2005... "Respected South Gippsland doctor, David Iser, has issued a warning about the adverse effects of wind farms on the health of neighboring residents. And he has called for further health studies to be carried out by authorities... "We are talking about 8 people having health problems as a result of the small Toora Wind Farm. There you have 12 turbines. It is proposed that there be 48 turbines at Dollar so you could have more than three times the number of health problems..."

- **Health, hazard, and quality of life near wind power installation: close is too close?:** Nina Pierpont, MD, PhD March 1, 2005... "Dizziness (specifically, vertigo) and anxiety are neurologically linked phenomena. Hence the anxiety and depression seen in association with other symptoms near wind installations are not a neurotic response to symptoms, but a neurologically linked response to the balance disturbances people experience from shadow flicker or low-frequency noise... Based on these health risks and hazards, turbines should not be placed within 1700 feet of any residential dwelling. Those living within 1/2 mile (2640 ft) should be apprised

are likely to experience very bothersome levels of noise and flicker, continue (though to a lesser degree) to a mile or more from the turbine.

- **Western Morning News and This Is Devon: 10-14-04...** Dr Amanda who has produced ground-breaking research on the effects of noise from wind turbines on people living near the Bears Down site explains why she continues her investigation further.

"I have heard from people all over this country; Cornwall, Wales and Cumbria; from France, Germany, Denmark, Australia, New Zealand and USA who are experiencing noise problems from nearby wind turbines. This is not an isolated problem and from the information I have been gathering, it is not a new problem either... Indeed prolonged exposure to low frequency noise and vibration is known to increase a person's sensitivity to the noise. Much research has been published showing the correlation between health problems and disturbance from noise.

Yet there has been no such research for wind turbines. An initial survey indicates that a problem exists and I feel this warrants further independent research and investigation. However, the wind industry puts it upon themselves to state that there isn't a problem without looking at the issues further. It is because of this that I have been working with a physicist and acoustic scientist, Dr David Manley, to try to confirm our observations.

- **Wind Farms 'Make people Sick Who Live Up To A Mile Away'** Catherine Milner, News Telegraph, 25/01/2004... "Onshore wind farms are a health hazard to people living near them because of the low-frequency noise that they emit, according to new medical studies.... Dr Amanda Hart, a GP who did the research, said: 'People demonstrated a range of symptoms from headaches, migraines, nausea, dizziness, palpitations and tinnitus, sleep disturbance, stress, anxiety and depression. These symptoms have a knock-on effect in their daily lives, causing poor concentration, irritability and an inability to cope'... Similar problems have been found by Dr I Osborne, a doctor in Moel Maclogan, a village in North Wales, where wind turbines were erected in 2002. She has presented a paper to the Royal Society of General Practitioners detailing a "marked" increase in depression among local people."

Noise

- **Studies on Wind Turbine Noise Raise Further Concerns:** Renew Energy Foundation, Press Release, Thur, 4th Aug 2005 (link is at the end of the page) ... "Hitherto, it has been assumed that low-frequency sound from wind turbines has not been a major factor contributing to annoyance because the blade passing frequency is of the order of one hertz where the human hearing system is relatively insensitive. This argument, however, can now be shown to obscure a very relevant effect: the blade passing frequency modul-

audible, higher-frequency sounds and thus creates periodic sound.

This means that residents near wind turbines have observed that, off the afternoon or in the evening the turbine sound acquires a distinct character, the rhythm of which is in agreement with the blade passing frequency, and that this effect is stronger for modern (tall) wind turb

-  **Wind turbines at night: acoustical practice and sound research**
G.P. van den Berg, Science Shop for Physics, University of Groning
Netherlands, presented at "Euronoise", Naples 1st March 2003... "In
modelling wind turbine sound very relevant atmospheric behaviour
'overlooked'. As a consequence, at low surface wind speeds such as
occur at night, wind turbine noise immission levels may be up to 15
higher than expected.

The discrepancy between real and modelled noise levels is greater for wind turbines. International models used to assess wind turbine noise at dwellings should be revised for this atmospheric effect. A discrepancy between noise forecasts and real noise perception, as a result of limited or even defective models, cannot always be avoided, even not in principle. Consequences can however be minimised if immission levels are measured at the relevant times and places. This relevancy is also determined by observation of those affected. It should always be possible to check noise forecast by measurement."

- **ISVR Consulting** has carried out projects on the generation and prediction of noise from wind turbine generators (WTGs) since 1991: "The case of an observer will be limited to a day-time viewing and might not consider which might arise due to noise from the wind turbines occurring during the night...The noise is produced aerodynamically from the blades, and mechanically from the gearbox and hydraulic pumps in the nacelle. In general, the noise levels are not high in absolute terms, the random nature of occurrence can be a cause of complaint. This is exacerbated by the fact that background noise levels during the night can be relatively low, even in rural and suburban areas. Wind farms are usually planned for rural areas and the problem is even greater."
- **Re: Something In The Air:** The noise perceived by those living within a mile or more of a wind farm, and particularly if downwind, is caused by a pressure wave that is generated each time a turbine blade passes the observer. Where several turbines operate in proximity the pulses move into phase, creating a doubling, tripling or more in the sound level, dependant on how many turbines are grouped together.

Several low-magnitude pulse trains thus cause noise with an unexpected strong impulsive character whenever they synchronise. This is inaudible to each individual turbine but is known to be the cause of considerable distress at greater distances. The effect is much more noticeable at night due to the greater differential between air flow at ground level and hub height.

also the greater sound-carrying capability of the cooler night air."

-  **Inadequate standards currently applied by local authorities to determine statutory nuisance from LF and infrasound:** 1st Marc Hazel Guest, "UK Noise Association", published by the "Journal of Frequency Noise, Vibration and Active Control", 2004, The paper e the barriers met by those who complain to their local authorities abo frequency noise.
-  **Wind turbine noise emission: wind speed measurements belo height give poor accuracy:** by Erik Rudolphi, "Ingemansson Techt AB", 1st March 2003...This paper highlights a case where wind spec measurements below hub height would have caused significant error
-  **Noise annoyance from wind turbines: A review** by Eja Pederse Halmstad University published by the "Swedish Environmental Prot Agency", 1st August 2003... The report reviews the perception and ar levels at noise from wind turbines in residential and recreational are Sweden.
-  **Do wind turbines produce significant low frequency sound** le G.P. Van Den Berg, presented to the "11th International Meeting on Frequency Noise and Vibration and its Control", Maastricht, 1st Sep 2004... This paper explores the nature of low frequency wind turbine
-  **Perception and annoyance due to wind turbine noise: A dose-relationship** by Eja Pedersen and Kerstin Persson Waye, "Dept. of Environmental Medicine", University of Gothenberg, published by 1 "Acoustical Society of America", 1st December 2004... The study se evaluate the prevalence of annoyance due to wind turbine noise and dose-response relationships.
-  **Wind Turbine Noise Issues: A Comprehensive Overview:** Ma 2004 by Catherine M. Lawton et al...Summary: This .pdf file provid comprehensive overview of wind turbine noise related issues and in following:

*Robert
Hammec*

Unbelievable denial: "The American Wind Energy Association, which represents the industry, says it knows of only a few complaints about noise."

Those noise easements must really be paying off. With all the noise complaints in the news in the last few years, how can they still deny the complaints? There are two of them

right in the article with that quote, including this:

Robert Larivee, a professor of chemistry at Frostburg State University in Maryland, says that's not his experience. He and his family have lived for the last three years under a windfarm built on Meadow Mountain, about a half mile from his home in rural Meyersdale, Pa.

Larivee said he had a professional engineer measure the noise, and found the windmills showed an average reading of 75 decibels _ about the level of noise from a washing machine.

The industry says the average windmill gives off only 45 decibels..."

"It's a low frequency, a rumbling like you are listening to a base drum," he said. "It's a constant background of 'whoosh, whoosh, whoosh.' He said he and his family haven't adjusted to the sound. 'If you've ever had a leaky faucet, you know it doesn't make a lot of noise, but it drives you nuts'... The windfarm scrambled his TV and radio reception, and the turbine blades have claimed the lives of countless bats that used to keep control over the population of mosquitoes and other summer insects.

Larivee's advice to residents of other rural areas planned for windfarms:
"Fight it."

The best, most sensible summary we've seen yet on what's wrong with the wind development situation in New York is the **Remarks Delivered To The Assembly Committee On Energy And The Subcommittee On Renewable Energy, Examining Policy And Implementation Plans For The RPS Program** on March 7, 2006 by an Ad Hoc Coalition Of Local Community Groups In Upstate New York. If you don't understand how anyone could be against wind development, [THIS will sum up](#) what all of the citizens' groups are concerned about.

This website is an ongoing project, created in response to a proposal by Noble Environmental Power, LLC to erect 67-70 turbines in the town of Wethersfield, NY, as well as a substation and overhead power lines. (Update 03-31-06: Noble now says they plan 86 turbines for the town). The turbines will be nearly 400 feet high (taller than the Statue Of Liberty), with a blade span as wide as the wingspan of a 747 jumbo jet.

Noble Environmental is a subsidiary of JP Morgan Partners and has their home office in Connecticut. Noble also has plans to erect 50-60 turbines in the town of Eagle, with the two projects joining together.

When you consider that the town of Wethersfield is only about 36.1 square miles in area, and Eagle only slightly larger, that puts into perspective what a huge project is being proposed. There are currently over 400 turbines planned for Wyoming County alone.

Save Western NY is a voluntary group of concerned citizens based in Wethersfield. Our

intent is to make sure the residents are aware of this project, which after a year, many still knew nothing about, and that they all have the opportunity to see the limitations and consequences of industrial wind power. While initially in favor of wind power, we have researched the issue extensively and became concerned that this project is likely to have a detrimental effect on our town and many homeowners' abilities to enjoy their homes and properties. We believe that the residents of Wethersfield have a right to know all the facts on this proposal and be involved in the planning from the beginning stages, but that isn't happening to date.

Developers reveal very little about the details and aren't likely to tell you the bad points of a project while trying to sell you on it, but a little searching reveals an abundance of evidence that there are clearly some serious problems with these wind "farms". It's only in recent years that they've been constructed in residential areas and the associated problems have resulted in over 300 opposition groups springing up around the world, many of them environmentalists formerly in favor of windpower.

The desire to reduce fossil fuel emissions is commendable, but it can compel otherwise sensible people to support windpower initiatives at any cost and without any investigation into potential consequences or how little wind turbines will actually contribute to that goal. However, with a little reading, you'll find some surprising facts that have come to light recently. We've gathered many studies and documents from what we feel are reputable sources and put them here in one place for convenience. We've also included a section on [Living With Wind](#), a collection of letters from wind farm neighbors. While these are not official documents, we've included them here because so many people from all over the world were saying the same things about living near industrial turbines.

We understand how landowners can find the lease money very tempting and many could surely use it, but they know not what they do to their neighbors. They're being deceived by developers, as we all are. Surely they'd feel the same if they were in our place. The reports on the health effects of turbines are cause for concern. Many of us have kids and don't want to take chances with their health and safety. Many are retirees and can't afford to go elsewhere. There's no free lunch here - there will be a price to pay.

The town will get a large amount of money from this wind project, but the developers from Connecticut will make many, many millions more. And money should never be our first consideration. Not one square mile of new countryside is being created. Instead, it's being steadily diminished, over-run by urban incursions, like satellite towers and wind "farms". We're being asked to exchange something increasingly precious that should go to our children and grandchildren for short term gain.

Please, at least read a few of these reports before you form an opinion on the issue. They don't take long to read. This is too important to limit your knowledge to wind industry advertisements. If we allow this and it turns out to be a mistake, it'll be too late - we'll be living with it for decades, as will our kids.

- [Excerpts from the Final Report of the Township of Lincoln Wind Turbine Moratorium Committee](#): This is a revealing report on living with turbines in a residential area. Twenty two turbines went online in Lincoln Township.

Wisconsin in 1999. The moratorium committee conducted a survey on the perceived impacts of the wind turbines that was sent out to all property owners residing in the township. The results were presented to the town board, two years after the wind factory construction.

- **Darmstadt Manifesto On The Exploitation Of Wind Energy In Germany:** This is a 6 page .pdf file (the last 2 pages are signatures). You will need Adobe Acrobat or Acrobat Reader to view it. The Darmstadt Manifesto was written by a group of professors and doctors in Germany, the world's leader in windpower. It claims that the exploitation of wind energy promotes the type of technology which is of no significance whatever for the purpose of supplying energy, saving resources and protecting the climate. To date, it has been signed by more than 100 professors and scientists.
- **Effects Of The Wind Profile At Night On Wind Turbine Sound:** G.P.van den Berg, Science Shop for Physics, University of Groningen, Netherlands-September 2003. This study examines turbine noise and why it's so much worse at night.

A Brief Cost-
 Benefit Analysis of
 Industrial
 Windpower

Foreign Oil and
 Global Warming

8. Wind technology is noiseless and creates few disturbances.

Tall wind turbines in concert with each other, especially those sited on prominent ridgetops, create profound noise reverberations extending out for more than a mile, sounding like "a boot tumbling in a dryer" or the revving jet engines on a runway. It is very difficult to predict noise levels in the mountains compared to flat land. Noise levels will be amplified in some areas and diminished in others depending on the shape of the terrain, the wind direction, the changes in wind velocity, and so on. The impact on people also depends on whether wind turbines operate in synchronization and whether the noise "beats" or throbs. This also depends on wind direction and velocity. Who will get bombed? Who knows? That is likely very hard to predict. The travel of sound waves and their behavior is similar to the way water waves travel. Most of us have seen how water behaves when waves enter into a gap or a split or channel of rocks in the ocean. The waves travel inward and pile up-and-up as they become restricted by the channel. The more the channel narrows, the greater the piling of the wave. Sound behaves in the same way. The more it piles up, the louder it gets.

A letter from Meyersdale, PA resident Bob Laravec, who lives 3,000 feet from the windplant, documents how he measured the noise over a 48 hour period. The results "showed an average reading of about 75 decibels during that period." "According to the EPA, noise levels above 45dB(A) disturb sleep and most people cannot sleep above noise levels of 70 dB(A)." Turbine noise is so irritating and disconcerting that it often causes people to seek medical attention, as Rodger Hutzell in Meyersdale had to do. Wind leases typically contain "noise easements" to protect the company from liability.

Noise from European windplants is a notorious and well-documented nuisance there. The wind industry is very aware of this problem but often tries to "hide" it by taking visitors during the day directly under the turbine where there is typically little noise or by conducting tours from May-September when wind speeds are typically lower.

A leading acoustical researcher of the noise problem, G.P. van den Berg of

Wind Rush

Dear Molly Ivins:

Better Energy Ideas

the University of Groningen in the Netherlands, believes loud aerodynamic sounds are generated when the moving propeller blade passes the turbine tower mast, creating sound pressure fluctuations. Such fluctuations may not be great from an individual turbine, but when several turbines operate "near synchronously, the pulses... may occur in phase," significantly magnifying sound. Van den Berg also notes a "distinct audible difference between the night and daytime wind turbine sound at some distance [more than one mile from the turbine]"—a finding consistent with the experiences of Meyersdale residents. (Both quotes were taken from G.P. van den Berg, Effects of the Wind Profile at Night on Wind Turbine Sound: Journal of Sound and Vibration (November 2004) 277:955-970.)

The problem is so acute and well-documented that the First International Conference on Wind Turbine Noise was held in Berlin, Germany on October 17 and 18, 2005. Organized by INCE/Europe in collaboration with the European Acoustics Association, the conference addressed "Wind Turbine Noise: Perspectives for Control"

Regulatory agencies and county zoning ordinances should insist upon acoustical field research to assess this noise phenomenon, requiring independent measurements and interviewing nearby residents. They should pay particular attention to noise measurement averages. Averages would not mean much if they were applied, say, to residents living next door to an outdoor pavilion during a rock concert. And it will not mean much to the residents of a rural community, either—who are used to the enjoyment of a quiet landscape.

An exemplary noise testing protocol for windplants was recently approved part of the Shawano County, WI wind ordinance. Other polities should strongly consider adopting this standard to protect citizens from windplant noise. This county had been targeted for industrial wind development and its citizens there, aware of problems with wind technology, vowed to protect the public by establishing regulations and testing protocols that the wind industry and enabling agencies now must follow.

Other nuisances industrial windplants may cause are:

- **Interference with television reception.**
The following weblink contains a March, 2004 BBC report, "The Impact of Large Buildings and Structures (Including Wind Farms) on Terrestrial Television Reception"—see:
<http://www.bbc.co.uk/reception/factsheets/docs/buildings.pdf>. "Wind turbines affect reception up to a maximum distance of 5km" is one of the key sentences in the report.
- **Shadow Flicker and Strobe Lighting.**
When turning with the sun behind them, turbine blades cast moving

shadows across the landscape and into houses in ways that may affect surrounding properties at a considerable distance; these are commonly described as a strobe effect within houses that can be difficult to block out. "Some people lose their balance or become nauseated from seeing the movement. As with car or sea sickness, this is because the three organs of position perception (the inner ear, eyes, and stretch receptors in muscles and joints) are not agreeing with each other: the eyes say there is movement, while the ears and stretch receptors do not. People with a personal or family history of migraine, or migraine-associated phenomena such as car sickness or vertigo, are more susceptible to these effects. The strobe effect can also provoke seizures in people with epilepsy." (Nina Pierpoint, PhD, MD in a personal conversation. Dr. Pierpoint was formerly a clinical professor of pediatrics at Columbia University and is now in private practice in Malone, New York).

- **Lightning and power surges.**
Wind turbines themselves may cause irregularities in the power supply as wind speed changes. Within the power grid, supply and demand must always be balanced; there is no storage of electricity on this scale. When the wind dies, there is less power (brown-out) until a plant using a more reliable resource powers up to increase production. When the wind gusts, there may be power surges. Residents living near the installation in Meyersdale, which came on-line in December 2003, had to replace stove elements and small appliances due to power surges which started at that time. Residents of Lincoln Township, Wisconsin near a wind installation noticed an increase in power surges associated with lightning strikes in their area after the turbines went on-line in June 1999. [Two computers protected by surge protectors and a TV set all in different houses, were simultaneously "fried" one evening when lightning struck a nearby wind turbine tower.]
- **Shoddy site construction practices can also cause serious erosion problems, especially if built along steep slopes. There is much documentation about how turbine blades throw boulder-sized ice that accumulated on the blade surface during winter. There are documented—and very dangerous—fires caused by malfunctioning turbine equipment.**

Health, hazard, and quality of life r wind power installations — How cl is too close?

Nina Pierpont, MD, PhD [1]

March 1, 2005

Falling over

A nacelle (generator and gearbox) weighing up to 60 tons atop a 265 ft. m tower, equipped with 135 ft. blades, is a significant hazard to people, lives buildings, and traffic within a radius equal to the height of the structure (40 beyond. In Germany in 2003, in high storm winds, the brakes on a wind tu failed and the blades spun out of control. A blade struck the tower and the nacelle flew off the tower. The blades and other parts landed as far as 16f mile) from the base of the tower. [1] (Note that all turbines discussed in thi are "upwind," three-bladed, industrial-sized turbines. "Downwind" turbines been built since the 1980s.) Given the date, this turbine was probably sma the ones proposed for current construction, and thus could not throw piece This distance is nearly identical to calculations of ice throw from turbines v blades rotating 20 times per minute (1680 ft). [2]

Fires

Most fires in wind turbines are started by lightning and fueled by up to 200 of hydraulic oil in the nacelle. Fire-fighting at 265 ft (26 stories) may not be with the equipment of a rural town. A fire may leave wind turbine controls

5/25/2006

malfunctioning until the equipment in the nacelle is repaired or replaced, is more susceptible to the kind of accident described above.

Lightning and power surges

Wind turbines themselves cause irregularities in the power supply as wind changes. Within the power grid, supply and demand must always be balanced; there is no storage of electricity on this scale. When the wind dies, there is a power (brown-out) until a coal- or gas-powered plant at some distance from the wind installation fires up to increase production. When the wind gusts, there are power surges. Residents living near a new wind turbine installation in Meyersdale, PA, which came on-line in December 2003, have had to replace stove elements and small appliances due to power surges which started at that time. Residents in Lincoln Township, WI, near a wind installation noticed an increase in lightning strikes in their area after the turbines went on-line in June 1999. Two computers protected by surge protectors and a TV set, all in different houses, were simultaneously "fried" one evening when lightning struck a nearby wind turbine tower. [3]

Flicker

When turning with the sun behind them, turbine blades cast moving shadows across the landscape and houses, described as a strobe effect within hours of which can be difficult to block out. Some people lose their balance or become nauseated from seeing the movement. As with car or sea sickness, this is because the three organs of position perception (the inner ear, eyes, and stretch receptors in muscles and joints) are not agreeing with each other: the eyes say there is movement, while the ears and stretch receptors do not. People with a personal or family history of migraine, or migraine-associated phenomena such as car sickness or vertigo, are more susceptible to these effects. The strobe effect can also provoke seizures in people with epilepsy.

In Lincoln Township, WI, two years after installation, 33% of residents 800 feet from the turbines found shadows from the blades to be a problem, 40% 1/2 mile away, 18% 1/2 to 1 mile away, and 3% 1 to 2 miles away (230 people sampled).

Noise

In the same survey in Lincoln Township in 2001, 44% of residents 800 feet from the turbines found noise to be a problem in their households, 52% 1/2 mile away, 32% 1/2 to 1 mile away, and 4% 1 to 2 miles away (229 people sampled). Under certain conditions the turbines could be heard up to 2 miles away. These numbers correspond well to measurements made by a sound engineer for a more recent 30 MW, 17 turbine installation on the Dutch-German border. Residents living 500 m (1640 ft, or 0.31 mile) and more from the turbines were reacting strongly to the noise, and residents up to 1900 m (1.2 miles) away expressed annoyance. The engineer found that measured sound levels were higher than predicted by standard models because of differences in daytime and nighttime wind patterns, and that annoyance was increased by the impulsive or rhythmic thumping of the sound, a pattern found at a distance from the

(documented at 1500 m, or 0.9 mile) but not immediately under or among turbines. [4] This was described as a "low pitched thumping sound."

Noise levels sufficient to prevent or interrupt sleep, even with windows closed, reported in dwellings close to wind power installations in all surveys. Low frequency sound, defined as 10-200 Hz, travels farther and comes through walls and obstacles because of its long wavelength; sounds in the range of 25- 150 wavelengths similar to room dimensions, and can reverberate in rooms. Low frequency sound is especially bothersome, according to the World Health Organization; [5] "Low frequency noise, for example from ventilation systems, disturb rest and sleep even at low sound levels."

"For noise with a large proportion of low frequency sounds a still lower [measurement] guideline (than 30dBA) is recommended." (This means 30 sound pressure using an "A" filter.)

"When prominent low frequency components are present, noise measurements on A-weighting are inappropriate." (An "A" filter, which filters out low-frequency sounds, is standard in loudness measurement.)

"Since A-weighting underestimates the sound pressure level of noise with low frequency components, a better assessment of health effects would be to use C-weighting." (A "C" filter filters out less of the low-frequency sound.)

"It should be noted that a large proportion of low frequency components in noise may increase considerably the adverse effects on health."

In other words, the World Health Organization recommends that threshold standards for noise in communities be set lower than 30dB (as measured with standard "A" filter) whenever the noise has a substantial low-pitched component, as it does from wind turbines. Again, this is because low-pitched noise is more disturbing and has a greater impact on health at low levels than higher-pitched noise. When measuring such noise, a "C" filter will give a more accurate measurement of loudness by including more of the low-frequency sounds.

Dr. Amanda Harry, a British physician, found (near a 16-turbine installation) that 13 out of 14 people surveyed reported an increase in headaches, and reported sleep problems and anxiety. Other symptoms included migraine, dizziness, palpitations, stress, and depression. [6] Noise itself can induce hearing loss and loss of balance in people with a previous history of noise-induced hearing loss. Since, when people damage their hearing through too much exposure to (or near) (machine) noise, the balance organs in the inner ear may also be damaged (a phenomenon known as the Tullio phenomenon). Dizziness (specifically, vertigo) and anxiety are neurologically linked phenomena. [7] Hence the anxiety and depression associated with other symptoms near wind installations are not a neurotic response to symptoms, but rather a neurologically linked response to the disturbances people experience from shadow flicker or low-frequency noise deprivation, by the way, also causes anxiety and depression. Older people, who often sleep less soundly, are more likely to have their sleep disturbed by turbine noise. They may also suffer more disturbances in equilibrium near turbines:

because of age-related problems with the function of the inner ear (e.g., dizziness and tinnitus: ringing in the ears) or from the nerves or parts of the brain receiving signals from the inner ear. It is noteworthy that among healthy people age 50 and over, 5% have chronic dizziness, and 24% tinnitus. [8]

Setback

Based on these health effects and hazards, turbines should not be placed within 1700 feet of any road or dwelling. Those living within 1/2 mile (2640 ft) should be apprised that they are likely to experience very bothersome levels of noise flicker, which continue (though to a lesser degree) to a mile or more from the turbines. At 2 miles, noise is sometimes heard, but few people are bothered. In Lincoln Township, WI, after two years with the turbines, 73% of people said they would not consider buying or building a house within a mile of the turbines and 23% wished to be at least 2 miles away (212 people sampled). It is significant that each of these setbacks (the first for hazard of falling objects, the second for noise) is supported by two unrelated pieces of data yielding the same result. For the data from two wind installations of different ages in different countries, one a resident survey and the other an engineer's measurements, yield the same setback distance at which noise stops being bothersome: at something greater than 1.5 miles. Thus the age or specific type of equipment is not relevant to the noise problem and specific measurements, properly done, support what neighbors of wind turbine installations are saying. In conclusion, based on these data, wind turbines should not be built within 1.5 miles of people's homes. Let it be understood, however, that there will still be health and life quality problems caused by wind turbines at this radius. People living 1.5 to 3 miles from a proposed turbine site should be notified of potential health and life quality effects, and for this they should be appropriately compensated.

NWW's Submitted comments to House of Representatives Appropriations Subcommittee on Energy & Water Development

March 31, 2006 by National Wind Watch

Summary:

National Wind Watch does not oppose funding of research and development for wind energy, but stresses that any increases in monies allocated be correctly focused. Most of any future research and development should now be focused on the detrimental impacts and mitigation techniques of wind development including, but not limited to: actual impacts on property values in areas where wind development occurs; actual net impacts on employment; life cycle analysis of environmental impacts (positive and negative); grid system stability and reliability under increasing penetration of wind, and within lower quality wind sites. Given the inherent and perceived conflict of interest, National Wind Watch recommends that the National Renewable Energy Laboratory NOT hold responsibility for such analysis but only be permitted to participate.

I. INTRODUCTION

National Wind Watch™, Inc. is a non-profit organization dedicated to raising awareness of the risks and related impacts of industrial wind energy development on the environment, economy, and quality-of-life. The organization represents local citizen groups and individuals seeking to protect

their property rights and community values, maintain nationally significant scenic resources and protect America's wildlife. The organization advocates an intellectually honest and scientifically sound assessment of the benefits and costs of industrial wind development with the objective of becoming a resource of information and assistance for individuals, local groups, and decision-makers seeking the facts about industrial wind power. Far too often, debates about wind power have overstated its potential benefits and ignored its tremendous costs.

II. SUMMARY OF POSITION

National Wind Watch does not oppose funding of research and development for wind energy, but stresses that any increases in monies allocated be correctly focused. Most of any future research and development should now be focused on the detrimental impacts and mitigation techniques of wind development including, but not limited to: actual impacts on property values in areas where wind development occurs; actual net impacts on employment; life cycle analysis of environmental impacts (positive and negative); grid system stability and reliability under increasing penetration of wind, and within lower quality wind sites. Given the inherent and perceived conflict of interest, National Wind Watch recommends that the National Renewable Energy Laboratory NOT hold responsibility for such analysis but only be permitted to participate.

III. SUPPORTING COMMENTS

During the debate leading up to passage of the Energy Bill in 2005 there was discussion as to whether the United States should adopt a Renewable Portfolio Standard or RPS. The Senate passed the RPS as an amendment, but the House voted it down. Senator Lamar Alexander correctly noted at the time that the RPS was "all about wind" citing factors that would limit implementation of other renewable sources including solar, hydro, and geo-thermal.

Senator Alexander also noted that, according to testimony before the Energy Committee and other sources, in order for the United States to achieve the standards in the RPS, it could "require building more than 100,000 of [the] new, massive wind turbines". Today, there are less than 7,000 such wind turbines in the U.S. The US Treasury Department is on record stating the wind subsidy, if renewed each year for the next five years, would reimburse wind investors for 25 percent of the cost of wind production and cost taxpayers \$3.7 billion over those 5 years (1). General Electric Wind, one of the largest manufacturers of wind turbines, experienced a 500 percent growth in its wind business in 2005 due to the renewal of the wind production tax credit in 2004. On a unit production basis, wind is subsidized more than 10 times any other energy source, yet contributes least to our energy security. Further, as the amount of wind generation increases, negative grid stability impacts grow exponentially.

National Wind Watch has watched the recent surge in wind development throughout New York, Pennsylvania, Virginia, and elsewhere in the US and the impacts of this development on rural communities. Town boards and local officials are ill equipped to evaluate the true impacts of these facilities. At the State level, some form of RPS has already been put in place in 23 states. This translates into additional State pressure on the community to embrace the wind

plant, quiet opposition, and degenerate the permit process.

In the face of this development, the September 2005 GAO Report titled *Impacts on Wildlife and Government Responsibilities for Regulating Developing and Protecting Wildlife* stated "... that the impact of wind power facilities on wildlife is more studied than other comparable infrastructure, such as communication towers, important gaps in the research remain. First, relatively few pre-construction monitoring studies have been conducted and made publicly available. It appears that many wind power facilities and geographic areas in the United States have not been studied at all." Where they have been studied (e.g. Altamont Pass in California) the studies find significant work to do to reduce continued and on-going decimation of wildlife, including endangered and protected species.

While requests for additional pre-construction studies may be made, the local communities often do not have the money to pay for original research at a site. In many cases, the research should not be confined to the limited hundreds of yards area where the turbines are located, but would involve a regional review to cover secondary impacts related to erosion, impacts to water quality, tourism and the economy, and bird migration patterns. In the absence of local funding, National Wind Watch has found multiple cases where wind companies have agreed to conduct such studies, but also assume authority over the parameters of the studies and, in so doing, predetermine the outcome.

Continued installation of wind turbines throughout our rural and mountainous landscapes without scientific, impartial review of the impacts of this industrialization would have devastating effects on some of the most precious ecosystems in the world. After decades of government subsidized research and implementation, it is time for the wind industry to no longer be treated as an 'infant industry'. Rather, it is time for the industry to start paying for much of its way, consistent with the maturation of the technology. Any money now should go to research, once and for all, the impacts of these massive turbines on our wildlife, open spaces, property values, health and safety of residents living in the vicinity of turbines, and the quality of rural life.

National Wind Watch respectfully requests that you deny further funding for wind energy research and development, and direct this funding to the detrimental impacts and mitigation techniques of wind turbines. We also recommend the National Renewable Energy Lab NOT be in charge of such analysis but only allowed to participate.

Press Releases

NWW Encourages Funding to Research Impacts of Commercial Wind Energy

Submits Comments to House Appropriations Committee

Rowe, MA (April 11, 2006). National Wind Watch submitted comments to the House of Representatives Appropriations Subcommittee on Energy & Water Development calling for funding to be redirected away from wind energy research and development (R&D) and instead focused on the detrimental impacts of commercial wind energy installations and possible mitigation techniques. The subcommittee determines annual spending levels for programs at the Department of Energy (DOE).

National Wind Watch stressed in its comments that "Continued installation of wind turbines throughout our rural and mountainous landscapes without scientific, impartial review of the impacts of this industrialization, would have devastating effects on some of the most precious ecosystems in the world." Further, it stated that after decades of government subsidized research and implementation, it was time for the wind industry to start paying for much of its way, consistent with the maturation of the technology. "Any money now should go to research, once and for all, the impacts of these massive turbines on our wildlife, open spaces, property values, health and safety of residents living in the vicinity of turbines, and the quality of rural life." National Wind Watch recommended that, given the inherent and perceived conflict of interest, the National Renewable Energy Laboratory not hold responsibility for such research but only be permitted to participate. The document submitted to the subcommittee can be viewed at <http://www.windwatch.org/documents/2342>. Similar comments will be submitted in the Senate.

National Wind Watch, a nonprofit corporation, seeks to promote knowledge and raise awareness of the risks and damaging environmental impacts of industrial wind energy development. Information and analysis on the subject is available through its website, www.windwatch.org.

In many cases, the research should not be confined to the limited hundreds of yards area where the turbines are located, but would involve a regional review to cover secondary impacts related to erosion, impacts to water quality, tourism and the economy, and bird migration patterns. In the absence of local funding, National Wind Watch has found multiple cases where wind companies have agreed to conduct such studies, but also assume authority over the parameters of the studies and, in so doing, predetermine the outcome.

Continued installation of wind turbines throughout our rural and mountainous landscapes without scientific, impartial review of the impacts of this industrialization would have devastating effects of some of the most precious ecosystems in the world. After decades of government subsidized research and implementation, it is time for the wind industry to no longer be treated as an 'infant industry'. Rather, it is time for the industry to start paying for much of its way, consistent with the maturation of the technology. Any money now should go to research, once and for all, the impacts of these massive turbines on our wildlife, open spaces, property values, health and safety of residents living in the vicinity of turbines, and the quality of rural life.

National Wind Watch respectfully requests that you deny further funding for wind energy research and development, and direct this funding to the detrimental impacts and mitigation techniques of wind turbines. We also recommend the National Renewable Energy Lab NOT be in charge of such analysis but only allowed to participate.

News from NWW

NWW Encourages Funding to Research Impacts of Commercial Wind Energy

Rowe, MA (April 11, 2006). National Wind Watch submitted comments to the House of Representatives Appropriations Subcommittee on Energy & Water Development calling for funding to be redirected away from wind energy research and development (R&D) and instead focused on the detrimental impacts of commercial wind energy installations and possible mitigation techniques. The subcommittee determines annual spending levels for programs at the Department of Energy (DOE).

National Wind Watch stressed in its comments that "Continued... [Read more »](#)

Mr. Michael Filion
Supervisor
Town of Clinton
7026 Route 11
Churubusco, NY 12923

Dear Supervisor Filion:

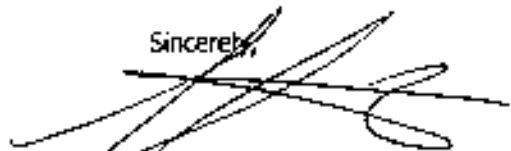

I am writing this letter to let you know that I strongly support the proposed Marble River Wind Farm and all the benefits it can bring to our community.

One thing we all know is that the wind doesn't blow anywhere quite like it does here. In my opinion it is our obligation as a community to take advantage of this unique resource that has the potential to benefit the entire community through royalties, local jobs, and community tax payments.

On top of all the local benefits it is also important to keep our eye on the big picture. With energy prices sky high and air pollution and global warming becoming increasingly an issue we all must contend with, I personally welcome this opportunity to small part of the solution.

We do appreciate the work and time the board has put in to make the right decision for the town. I hope this letter helps to make your decisions that much easier.

Sincerely,

John Osakawicz
Churubusco

WE HAVE BEEN PAYING QUITE LARGE SUMS OF MONEY FOR PROPERTY TAXES OVER THE YEARS. THE OPPORTUNITY OF WIND ENERGY AND THE MONETARY RETURN OFFERED IS OF GREAT INTEREST TO US. WE HAVE CONSTANTLY BEEN TELLING HORIZON WIND COMPANY THAT WE WOULD LIKE ADDITIONAL TURBINES. THEY AGREE THAT WE HAVE SUFFICIENT LAND TO ACCOMMODATE MORE TURBINES.

WE UNDERSTAND YOUR INTEREST IN SATISFYING SOME PEOPLE WHO LIVE NEAR TO THE TOWN.

IN RESPECT TO THEIR OBJECTIONS WITH APPEARANCE, NOISE, ETC. OF WIND TURBINES, ALL OF OUR LANDS ARE VERY REMOTE, AND TO THE BEST OF OUR KNOWLEDGE THERE IS NO OPPOSITION IN OUR AREA IN RESPECT TO THE ABOVE OBJECTIONS. NOT VERY OFTEN DOES AN OPPORTUNITY SUCH AS THIS COME TO SUCH A REMOTE AREA AS OURS

WE SINCERELY REQUEST THAT YOU DISCUSS THE POSSIBILITY OF MORE TURBINES IN OUR REMOTE AREAS WITH HORIZON WIND COMPANY. IT SEEMS THIS COULD ONLY BE A WIN-WIN SITUATION FOR THE TOWN AND OURSELVES. WE THANK YOU IN ADVANCE.

Dear town board members:

As a tax payer and land owner in the Town of Clinton I am writing this letter to let you know I strongly support the proposed Marble River Wind Farm.

Various areas of this country are sources of lumber, coal, petroleum, water power and other natural resources. Each one of these gifts of nature must be developed wisely, with great consideration to the impact to the environment.

Here in Clinton it is time to step into the twenty-first century and develop one of its greatest natural resources, clean, renewable, free, and constant, WIND.

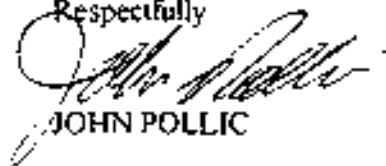

The income to the land owners, project participants, school systems, and municipalities is significant. For example, a participant with marginal income could benefit from an increased quality of life or a dairy farmer could enjoy a well-earned retirement in his later years.

Later in the life of the project our obscene tax bills may lessen.

Yes, the turbines are visible, but let it be a sign the Town of Clinton is stepping up and contributing clean and nonpolluting energy to New York State for 2006 and beyond.

In so far as additional turbines in the northern corridor such as the Liberty Pole Rd. If the land owners are in favor of such a possibility, why not explore the feasibility of adding to the project?

Respectfully

JOHN POLLIC

136 Liberty Pole Road
Churubusco, NY 12023

May 19, 2006

Honorable Michael Filion, Supervisor
Town of Clinton
and Honorable Council Members
Clinton Town Hall
23 Smith Street
Churubusco, NY 12923

Dear Supervisor Filion and Council Members:

We would like to take this opportunity to convey to you our support for the proposed Marble River Wind Farm. It appears to be an endeavor that will benefit landowners individually and the Town of Clinton as a whole.

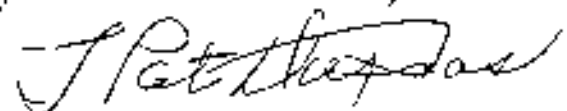

Wind is certainly an inexhaustible resource in our town, which can be put to good use through the development of a wind farm. If as a bi-product, jobs are created, the cost of energy is lessened, and the town and school taxes are reduced, then by all means this is a project that should receive our whole hearted support. The more wind towers that are constructed, the better it will be for us all.

Hopefully, with our support, and that of many of our friends and neighbors, your decisions concerning the Marble River Wind Farm will not be difficult to make.

Sincerely,

Elaine M. Dupras

L. Pat Dupras

L. Pat Dupras

May 15, 2006

Dear Town Board Members:

My name is Glenn Fountain and I currently reside in Plattsburgh. My wife Faye and I highly support the proposed Marble River Wind Farm. We are land owners in Churubusco having 430 acres, and our intentions are to be a residents upon my retirement which is 18 months from now. We believe that taking advantage of future resources for the community would be beneficial all around. Creating jobs, royalties, tax payments, etc. in our community of Churubusco, would be a big step in the right direction. With the price of fuels, rising every day WIND as an alternative power source is the way the people of the United States must go. We are too dependent on foreign countries for our fuel resource. Respectfully with all the hard work and time the board has put forth, I hope you make the right decision and go ahead with the Wind Farm project. This would also benefit our children and grandchildren with future energy and pollution problems.

Sincerely, *Glenn Fountain Sr*

Faye Fountain

15 May 2006

Dear Town of Clinton Board Members,

A few years ago my wife, Betty, and I purchased 100+ acres of "habitat" in Churubusco. I had hunted in Churubusco with local friends for some time and gotten a great deal of enjoyment from those experiences. I like the area very much.

Subsequent to the land purchase in 2003, I have gotten to know my immediate neighbors, Jerry Miller and Mike LeClair, fairly well. They are good people and great neighbors. I talked with both on a recent trip to New York and they both assured me that they were in favor of the Marble River project.

Although I am not a resident of New York, I am a taxpayer and I care about the future. I am in favor of the Marble River project and all the community benefits it entails.

I do appreciate your efforts and I hope this brief letter helps in that all important decision you will be making for the Town of Clinton.

Sincerely,

A handwritten signature in cursive script, appearing to read "Greg Sands".

Greg Sands

Dear Town Board Member,

I am writing to each of you to express my support for The Marble River Wind Project. I live in the Central New York community of Sauquoit which is approximately ten miles South of Utica and about ten miles northeast of The Madison Windpower Project. I believe the Madison project was the first modern wind project in New York; being constructed and put into service in 1999 with seven 1.65 megawatt structures.

I am originally from the Ellenburg area having moved to Central NY in 1977 and own land in the Town of Clinton in partnership with my brother and former brother in law. I see the proposed wind project as a huge opportunity for the area for the following reasons:

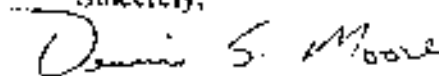

- The project will bring good paying jobs for local residents and revenue to the area before, during and after construction. I recently witnessed the construction boom in the Lowville area last year as workers occupied local hotels and restaurants. Local people were employed and local concrete companies, excavators, contractors all benefited in the construction of The Maple Ridge Project. After the construction phase people and jobs are and will be in place to maintain these facilities.
- The project will decrease the tax burden for local residents as it has in Madison and Lowville areas. I recently spoke with the Business Manager of the Madison Central School District and learned they have partnered with their local project since 1999 receiving payments that have reduced local taxpayer's burden.
- It is an opportunity for the area to assist in this Nation's development of clean renewable energy. As you have seen recently by skyrocketing energy prices this nation needs to develop other sources of energy and wean itself from dependence on foreign sources.
- It is an opportunity to teach area children and residents that we can harness a resource that has at times been a curse. My family and I attended the open house held in the fall of 1999 by Pacific Gas and Electric, the Madison Windpower Project developer, at the Madison Central School. Approximately five thousand people attended and were bused to the site on Madison Central School buses to observe the windmills in operation and learn all the facts about them. These seven windmills along with nineteen in Fenner have remained a source of interest and tours to this day.

My experience with the Madison and Maple Ridge Wind Projects makes me question the objections of project opponents. The claims heard from opponents when I

attended local Town Board meetings in Clinton and Ellenburg are not being expressed by local land owners and wind project neighbors in this area.

I appreciate your time and effort and urge you to support this project which will greatly benefit the area!

Sincerely,

A handwritten signature in cursive script that reads "Dennis S. Moore". The signature is written in black ink and is positioned to the right of the word "Sincerely,".

Churchusco N.Y.

May 23, 2006

Town of Clinton Supervisor and Councilmen

I am writing this letter of support for the maple River wind Farm.

We have the wind, and if we can benefit with local jobs, and help us with community tax's, I think it will help everyone.

In my opinion what I see on the maps, in this nothead of town, the wind farms on Liberty Pole Rd looks far enough away, it should not be a bother.

I appreciate the work and time the board has put in to make the right decision.

I hope this letter helps your decisions ^{much} easier

Sincerely

~~Gerald S. Miller~~

Policies of New York Farm Bureau regarding the siting of energy facilities on agricultural land

We encourage the development of more energy from wind and solar power sources.

We recommend companies with rights-of-ways on farmland identify the location of their underground transmission lines and/or pipelines.

When siting utility right-of-ways, adverse agricultural effects on all farms should be minimized by:

a. Judicious routing to help avoid construction and operation through farmsteads, croplands, orchards, and sugarcane operations;

b. Utilization of state-of-the-art mitigation practices and full rehabilitation of all agriculture-related lands which are not otherwise avoided;

c. Utilization of qualified agricultural specialists to maintain on-going field contact with all affected farmers and other organizations from project design stage through final land rehabilitation;

(NYS DAM has qualified personnel whose job it is to do this work and their involvement should be included in local regulations governing the construction of any such projects)

d. Ensuring just compensation for right-of-way easements and damages; and

e. Consideration of all other viable routing options with preference being given to the use of previous utility right of ways and highway medians.

Productive farmland or aquaculture/fishing grounds should not be taken by eminent domain for the construction of a power generation plant nor should this plant's location negatively impact neighboring productive farmland or aquaculture/fishing grounds.

Public utilities should be required to investigate all complaints of stray voltage on farms within five (5) working days. The utility

should be required to isolate or place a blocker on grounded lines if it is found that the utility system is imposing a voltage onto the customer system at a level at or above known levels of concern.

We support an amendment to the current Dig Safe New York Law 16NYCRR, Part 753 to read: "All utilities will be buried a minimum of (48") forty-eight inches deep and that Dig Safe NY will verify this with a letter to each agricultural property owner who has utilities crossing their property, and that it will relieve any responsibility from the owner if the utilities are disturbed".

We recommend that priority should be given to projects promoting naturally renewable sources of energy. Assistance from government (such as NYSEERDA) for such projects should be prioritized. Local governments should receive incentives from the state and federal government for promoting such projects locally.

We support property tax exemptions for those farms that have solar or wind energy systems or farm waste energy systems.

All aspects of agriculture should equally be eligible to participate in government programs meant to protect the environment and/or conserve energy.

Wind towers should be allowed on private property.

Towns of Clinton DEIS hearing regarding Noble Environmental Power's request for permit to erect a wind farm project.

Good evening my name is Kirby Selkirk. I'm a Field Advisor for New York Bureau and I'm here on behalf of Clinton County Farm Bureau.

At its regular meeting on May 11, 2006 the Clinton County Farm Bureau Board of Directors passed a resolution concerning the establishment of commercial wind power projects.

The resolution reads: *Be it resolved that the Clinton County Farm Bureau fully supports the establishment of commercial wind turbines on our member's farms.*

This resolution is intended to support those farmers who wish to participate in the projects being proposed for their property.

This is in keeping with the policies of New York Farm Bureau and American Farm Bureau Federation which support and encourage the establishment of renewable energy sources, including wind, solar and bio-fuels. I've included a copy of their statement for you.

Environmentally, the turbines are great for farmers - you can crop right up to the turbine and the development company takes great care in restoring the farmland impacted by construction. At the end, there is only a road that leads to the turbine.

This project and others could provide 6% of our nation's electricity, or about the same as hydropower, by 2020. A New York study found that if wind energy supplied 10% (9,300 MW) of the state's peak electricity demand, 65% of the energy it displaced would come from natural gas, 15% from coal, 10% from oil, and 10% from electricity imports. As many as 215,000 new jobs would be created by adding 50,000 MW of neComment # 235 lions in the U.S. - a \$50 billion investment that could provide electricity for as many as 15 million homes with 39 million people.

Last year wind energy generated over 17 billion kilowatt-hours in the U.S., enough electricity to power 1.6 million homes. A single wind turbine can provide \$4,000 - \$7,000 each year in farm income and only use 2-5 percent of the land for the turbine and access road. Each megawatt (MW) of wind energy capacity installed in the U.S. provides 2.5-3 job-years of employment. In 2006, U.S. wind farms will be saving over 0.5 billion cubic feet of natural gas per day. To generate the same amount of electricity as a single 1-megawatt (MW) wind turbine, a traditional fossil fuel or nuclear power plant requires, on average, withdrawing about 60 million gallons of water per year from a stream or river. To generate the same amount of electricity as today's U.S. wind turbine fleet (6,740 MW) would require burning 9 million tons of coal (a line of 10-ton trucks 3,437 miles long, from Seattle to Miami) or 28 million barrels of oil each year.

I have prepared a list of the New York Farm Bureau policies pertaining to the siting and construction of energy facilities. These address our concerns of protecting the farmland. I will cite only one.

When siting utility right-of-ways, adverse agricultural effects on all farms should be minimized by:

a. Judicious routing to help avoid construction and operation through farmsteads, croplands, orchards, and sugarbush

operations;

b. Utilization of state-of-the-art mitigation practices and full rehabilitation of all agriculture-related lands which are not otherwise avoided;

c. Utilization of qualified agricultural specialists to maintain on-going field contact with all affected farmers and other organizations from project design stage through final land rehabilitation;

(NYS DAM has qualified personnel whose job it is to do this work and their involvement should be included in local regulations governing the construction of any such projects)

d. Ensuring just compensation for right-of-way easements and damages; and

e. Consideration of all other viable routing options with preference being given to the use of previous utility right of ways and highway medians.

I will submit written copies of this our policies and the resolution from Clinton County Farm Bureau.

My name is Cassandra Burl. I live at 498 Campbell Road. My family the LaClair's have lived in the town of Clinton since the early 1900's and probably even longer. At present we have four generations living side by side. When I got married I had my husband move here because I knew that this was the type of place to raise a family. Even with the discussion of wind mills moving in we have not changed our minds.

My family has been having discussions on wind energy for over three years so this is not a subject that we have not done our homework on. My sister did her masters thesis on wind energy at RPI and is currently working as an environmental engineer. She loves this town as much as those that live here on a daily basis and also has a vested interest in it as 95% of her family resides here. I trust that she would not promote wind energy if she felt it were unsafe in any way. So I take offense to those that say we have to be idiots to want wind turbines here. We have taken the time to do our own research on the proposal. We have taken the time to visit the wind farms and discuss with the residents how they feel. I call that smart and being well informed.

Many have said that this is new and we should wait to see how this works in other locations and do more research. Wind energy is not a new concept. Denmark has been using wind energy since the 1970's. If it were unreliable how could at least 20% of their power come from the turbines? How much longer should we wait for a clean form of energy?

The most important investment that my husband I will ever make is in the future of our children. The wind companies are offering us a chance to first and foremost preserve the environment for our children. The energy is renewable and free. They are offering money to our school district that could be used to fund programs that have been lost due to budget cuts or start new programs that will keep our youth motivated to learn and stay in school. Last but certainly not least there would be money on the town level that would enable our town to ensure better highways,

possible programs for our elderly and start programs for the youth of our area where none exist right now.

I have gone to lots of meeting where one of the major concerns for those against the turbines is that they are going to lose money based on the value of their homes if they were to try to sell. You keep asking who is going to compensate you for your loss. Let me ask you who is going to compensate the land owners for their loss if the project doesn't go through? The farmer doesn't ask you if he can grow wheat or corn. Why should he have to ask to harness the wind and ensure a cleaner environment for everyone?

The argument has been raised that turbines are unhealthy. The turbines will affect asthma and allergies. That was a major concern for my husband and I as our daughter suffers from severe allergies and asthma. Our pediatrician said she had no concerns with the turbines being in our area.

In case you wondered I am 100% for the wind turbines as is the rest of my family, and can see the benefits that come with it. We are looking at this proposal with our eyes wide open. I ask that the board not cut the proposed number of turbine but to accept the project as is. If you were to cut the project back who would you cut from the farm that is getting 1 or 2 or the farm getting 3 or 4? Make the right decision and keep the project as is and take a step in the right direction for our future and that of our children.

Dear Mike:

I have owned property in Chubbuck for about 4 years. I have become very fond of the area and its people. I would like to express my opinion on the wind situation I am for the wind farm because I think it would be a very good thing for the community. It would provide much needed energy and income for the town.

I am from Barre, Vt. which is known for its Granite. We are fortunate enough to have granite there and it has become a high commodity for the area with jobs & income. Chubbuck is fortunate to have even a better commodity, Wind! Better because it's clean, safe, and beautiful.

Honestly the majority of the people in town will be for the wind farm, because I am totally for it for its environmentally safe factor.

Thank you

Dr. Anthony Cassoni

Dear Town Board Member(s)

I am writing this letter to let you know that I (we) strongly support the proposed Marble River Wind Farm.

One thing we all know is that the wind doesn't blow anywhere quite like it does here. In my opinion it is our obligation as a community to take advantage of this unique resource that has the potential to benefit the entire community through royalties, local jobs, and community tax payments.

On top of all the local benefits it is also important to keep our eye on the big picture. With energy prices sky high and air pollution and global warming becoming increasingly an issue we all must contend with, I personally welcome this opportunity to be a small part of the solution.

We do appreciate the work and time the board has put in to make the right decision for the town. I hope that this letter helps to make your decisions that much easier.

TO: Town of Clinton Town Board: Public Hearing
FROM: Dinah Miller 1311 Clinton Mills Road, Churubusco, NY 12923
DATE: May 25, 2006
RE: Commercial Industrial Wind Complex's Noble Power & Marble River, LLC. Draft Environmental Impact Statement

Certified Mail: 7004-0750-0001-0015-2435

Please place in the permanent public record for the above public hearing.

My husband Daniel, our 3 ½ y.o. son Dane, and I reside at 1311 Clinton Mills Road, Churubusco, New York 12923. We purchased our home in 1994 and are mortgage free. Our residence is a Sears and Roebuck house that came on the Rutland Railroad Train in 1923. My husband and I constructed a recording studio next to our home because of the silence here. Who is going to be responsible for our lost revenue from our recording studio when we no longer can record? Who will take responsibility when the noise from the turbines drives us from our home?

I OPPOSE BOTH WINDPARKS FOR THE FOLLOWING REASONS.

1. The noise impact studies conducted by professionals not related to this project state that no turbine should be placed closer than 1.5 miles from a residence. The Town of Clinton ordinance has these turbines placed 1200 feet.
2. These wind companies are the biggest con job that the Town of Clinton has instituted. These corporations targeted this area for the land, no zoning, poverty levels, and ignorance of the Town of Clinton Town Board.
3. Every few months Noble Power and Marble River, LLC changes their corporate papers. How will ongoing changing of their corporations decrease their liability and increase the Town of Clintons?
4. Neither the Town of Clinton ordinance nor Noble's or Marble River, LLC. Draft Environmental Impact Statement mentions the International Border with Canada. Nor do they have approval from US Department of Homeland Security or the US Department of Defense to construct this Windpark. But, hey, who cares about National Security, eh? It is listed in wind turbine lease holder agreements that wind turbines kill telecommunications. Who cares about international border security and national security? I have sent information to several Federal agencies. I have received documentation from these Federal agencies reporting they have been in contact with the Town of Clinton, Daniel Spitzer, and the engineering firm of Conestoga-Rovers. What's interesting is this

documentation is not in the engineers reports in the Draft Environmental Impact Statements.

5. Noble and Marble River did a presentation at the Clinton County Planning Board and informed the board that they would construct 136 turbines. The two companies have stated in paperwork that the total number in the Town of Clinton as of last month is 176. How many more lies will be presented by these wind companies that you will ignore?

6. If the Town of Clinton Town Board had any intelligence it would be able to read scientific data informing you that these turbines should not be less than 1.5 miles from residence. It was your responsibility as the elected officials to make this community safe. You have failed in your but that doesn't surprise me. You believed everything Daniel Spitzer told you and he is paid by the wind companies. You believed the engineer who was paid by the wind companies and it was Daniel Spitzer who brought them here. The Town Board has been a puppet for big business.

7. The payment amounts to the Town of Clinton are unacceptable. We were promised by all parties that we would have no land or school taxes. More lies from the wind companies and the Town of Clinton Town Board.

8. How many people support wind power if they weren't being paid by the wind companies? How many people support wind power after they have stayed 24 hours 1200' from one when the propellers are rotating in 15 mph winds?

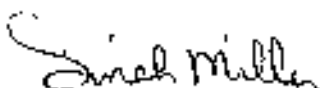

9. Why was there no mention in the Draft Environmental Impact Statements in regards to the American Indian Burial Grounds?

10. What ignorance has built, God will destroy. That's what happens when you build 40 story projectiles on an active earthquake plate.

I feel sorry for the ignorant people who believe the money justifies the placement of these turbines in the Town of Clinton. And for the 99.99% of Catholics who reside in this town, they obviously didn't read Timothy 1 Chapter 6:10 "Money is the root of all evil." Evil has come to this town.

In conclusion, I am glad you have destroyed this community. It will be your lasting legacy and I am laughing out loud.

Sincerely,

Dinah Miller

20. May. 2006
Churubusco, NY

To: Town Board, Town of Clinton
Michael Filina, Supervisor

Please enter the following remarks into the public record for hearings in the Town of Clinton (scheduled for May 25 in Churubusco, NY) re: The Marble River Wind Farm Draft Environmental Impact Statement (DEIS).

Ladies and Gentlemen:

I regret that I cannot attend this meeting, but I am traveling at this time; I would like, however, to make some remarks about the DEIS that you are considering.

In general, I found the summary document by CSA as well as the longer document submitted by Marble River to be good generally. Details were addressed in most places. Still, I would like to point out the following problems that should be addressed in the final impact statement (FEIS) by Marble River.

1) First, in the tan CSA summary document:

In the **summary document, page six**, there is no mention made of bird species that carry on courtship displays each spring. We know (and DEC wildlife biologists like Mark Weithal in Albany point out) that species like bobolinks and woodcock make vertical flights that easily soar above structures like the turbines. We strongly hope that you will address this problem by proposing **close cropping of grass in areas surrounding the turbine bases during the spring months** somewhere in this section. That may keep displays around the turbines to a minimum.

On page seven, you keep the **lighting (red/white) minimal to reduce the potential attraction to night migrations** and suggest using flashing lights with a long off-cycle. **Are red lights better than white lights for this? Will you use mostly red? Mostly white?**

Also in the **CSA summary document** and in the related Marble River volume one, you should specifically address the effects on amphibian

populations. I was hoping to find such discussions in the first ten pages of the summary but I did not. Of course you know that we have substantial amphibian populations, with a number of species of frogs, toads, peepers, etc., in this area, something that is special for NYS.

There are numerous waiver requests mentioned in tables in Appendix C in the Doyle letter. That a required 500-foot setback be replaced by a setback of only 25 feet is certainly a substantial change, for example. Yet reasons for the waiver requests are not included here. They should be.

There seems to be no mention of periodic servicing of the turbines in the DEIS summary, unless I missed it. How frequently will the turbines be serviced? How often will the mechanisms need replacement? Will you do the repairs in such a way as to minimize disturbance, i.e., in the summer, but not during the deep winter or during a wet spring? What disturbances do you anticipate? How heavy will the equipment be?

2) In Volume 1 of the Marble River full DEIS:

On page 50 in section 3.2.3 general mitigation methods like haybales, barriers, and drainage ditches are discussed. However, you state that this is not a final mitigation proposal. Shouldn't the final mitigation proposal be included? When?

On page 45, where you discuss the interconnects and describe the access roads, the clearing corridors and the 15-foot wide corridors disturbed by the electrical interconnect equipment, you state that the soil will be evacuated to only three feet. Then you propose burying interconnects to align with access roads or crane walks. I suggest that you consider avoiding access roads entirely in certain areas where the access roads actually cross wetlands as they do so often in the town.

On page 46, you quantify wetlands impacts in such a way as to keep the numbers small, e.g. 22.5 A of DEC wetlands, 54.5 A of DEC wetland buffer. It's not clear whether the 41 A of construction related wetland impacts are separate or included, the 10.4 A of access road impact, as well. Could you simply express the total of all impacted acres somewhere here, excluding the overlaps?

Following page 46 you state that the final wetland delineations will be submitted sometime soon to the US Army Corps of Engineers and the DEC, that there will be site visits, and that further wetlands impacts will be minimized or avoided as a result. Shouldn't this have been done prior to the submission of the DEIS? This seems to make some parts of the DEIS look premature. Certainly you should address this in the FEIS.

Please enter this statement in the public record, and thank you for the opportunity to bring my concerns before you.

Respectfully,

Martin H. Garrell

Review of the Noble Environmental DEIS for Clinton, NY

Nina Pierpont, MD, PhD
 19 Clay St.
 Malone, NY 12953
 (518) 483-6481

May 31, 2006

RECEIVED JUN 03 2006
 Donald McComb
 Town Clerk
 9:10 AM

Abstract:

- 1) Benefits claimed for wind power are **inflated by failure to use realistic, published efficiency figures. No evidence is presented to support industry claims that production of wind-generated electricity lessens fossil fuel consumption.**
- 2) The **quality of the DEIS is superficial and presentation is deceptive. The avowed goal of the company which prepared the DEIS is fast permitting, not protection of environment or community.**
- 3) Safety with regard to turbine fires, lightning strikes, and ice or blade throw is not adequately addressed.
- 4) **Data on turbine stability in the presence of earthquakes is not presented. The DEIS preparers failed to note an earthquake of magnitude 5.1 which occurred 33 miles from the proposed project area in 2002 and caused \$4 million worth of damage, and another earthquake of magnitude 3.7 five miles from the proposed Project area this year. Setback of 500 ft. from roads and 587 ft. from on-site buildings, as specified in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances, is not adequate to protect the public should one of these slender 400 ft. structures with 100 tons of equipment near the top fall over.**
- 5) **Noise standards adopted in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances do not comply with community noise standards put forward by non-industry agencies such as the NYS DEC or the World Health Organization, and as such will not protect the public from the health impacts of excessive community noise. Noise modeling did not use up-to-date models of the known distant propagation of annoying noise from wind turbines under conditions of nighttime atmospheric stability. Noble Environmental's acoustics consultant is well aware of these models and was negligent in not requiring their use. While recognizing that wind turbines produce low-frequency noise, the acoustics consultant appears to be ignorant of the medical research literature on the brain, lung, and heart pathology caused by long-term exposure to noise at frequencies too low to be heard.**
- 6) **Shadow flicker produces symptoms of motion sickness in susceptible people and has the potential to trigger seizures in individuals with epilepsy.**

- 7) Bird and bat studies are inadequate with regard to standards communicated by USFWS to Noble with regard to migratory birds, threatened and endangered species, and eagles. No population figures can be derived from the data obtained and presented in the DEIS. Multi-year studies were not performed. There is no adequate baseline created here by which to use this wind turbine installation to study the effects of wind turbines on bird and bat populations.
- 8) The non-avian wildlife section shows incompetence. As in (7), no population data is presented on which to base studies of the effects of wind power development on game species such as deer and bear.
- 9) It is not clear in the DEIS that appropriate state and federal (Army Corps of Engineers) oversight and permitting has taken place with regard to wetlands within the project areas. In fact it has not, according to the responsible Army Corps of Engineers official I spoke to on May 31, 2006, at which time review of the Clinton Project application was in the early stages and review of the Ellenburg and Altona Project applications not yet under way. Permits are required for all activities impinging on any wetland or stream connected ultimately to a navigable waterway. Federal review under the Fish and Wildlife Coordination Act and the National Historic Preservation Act are also required, triggered by projects falling under Army Corps of Engineers jurisdiction.

Introduction:

I am a graduate of Yale (BA 1977, Biology), Princeton (PhD 1985, Population Biology), and Johns Hopkins (MD, 1991). Population Biology is ecology, evolution, and animal behavior. I studied the behavior and ecology of Amazonian birds, spending two years in the field in South America forests. Besides this, I did a year-long (1985-6) post-doctoral fellowship in ornithology at the American Museum of Natural History, NYC. I have lived in this region (Franklin County) of NY State, where I practice behavioral and developmental pediatrics, for nine years. I am familiar with local ecology as well, as a physician, with health and safety issues.

It is "the intention of the Legislature that the protection and enhancement of the environment, human and community resources should be given appropriate weight with social and economic considerations in determining public policy, and that these factors be considered together in reaching decisions on proposed activities" (SEQRA 617.1 Authority, intent, and purpose.). The first issue to be considered here is thus whether there is sufficient social and economic gain anticipated from this project to make it worth the environmental impacts it will have.

SEQRA emphasizes the importance of cumulative impacts from simultaneous or subsequent projects in addition to the specific current project. Industrial wind generating installations are in the planning stages across northern New York State from Cape Vincent to Plattsburgh. The first wave of a large installation has already been built on the high ground east of Lake Ontario (Tug Hill Plateau, Lewis County). The current Noble Environmental applications represent only "Phase 1" in the locations of Ellenburg, Clinton, and Altona. Between Noble Environmental and Marble River, the two companies operating in Franklin and Clinton Counties, 860 turbines are currently proposed (data from applications to the New York Independent Systems Operator [NYISO]).¹ The cumulative viewpoint significantly alters how we view issues of land use, agricultural land preservation, community character, and impacts on wildlife. In the

¹ www.nyiso.org. See "NYISO Interconnection Queue," under NYISO Planning, under the Services drop-down menu.

Noble Environmental DEISs, the cumulative viewpoint is limited to their own current projects and does not consider the wider problem of many hundreds of wind turbines spanning the length of the highlands above the St. Lawrence River Valley from Lake Ontario eastward. Moving further west, turbine installations are also in planning south of Lake Ontario and throughout rural upstate NY.

I will address first the issue of social and economic benefits, and then the following areas in which I have expertise and find Noble Environmental's assessment of environmental risks to be inadequate or faulty: creation of hazards to human health, noise levels, wildlife effects (including game animals and migratory birds), and wetlands.

1. Assertions about the project's public benefit

Noble Environmental makes assertions about the positive effects its product, wind-generated electricity, will have on reduction of emissions from other power plants (DEIS p. 5 and 1-15). These assertions are based on the stated assumption (p. 1-15) that this 102 MW windplant (68 turbines x 1.5 MW per turbine) will indeed deliver 100 MW of electric power to the power grid. This assumption is inflated and deliberately deceptive with regard to the project's public benefits. General Electric, the turbine manufacturer, in a report to the New York State Energy Research and Development Authority (NYSERDA) on March 4, 2005, stated, "Capacity factors of inland wind sites in New York are on the order of 30% of their rated capacity. Their effective capacities, however, are about 10% [of rated capacity], due to both the seasonal and daily patterns of the wind generation being largely 'out of phase' with the NYISO load patterns."² The erratic nature of wind and the impossibility of matching supply to demand with wind-generated power make it the least preferred power source for the Independent Systems Operator (New York State power grid), which does not want the proportion of wind-generated power to approach current goals of the NYS Renewable Portfolio Standard (25% for all renewable sources) because of grid stability issues and because the NYISO's need is for capacity (power generated at the specific time to match needs) not energy (power generated at other times) (testimony presented at the RPS Hearing of the Energy Committee of the NYS Assembly, March 7, 2006). NYSERDA further states that wind power can produce, at most, 1.7% of NY State's electricity needs.³ Noble Environmental is aware of these limitations and writes with intent to deceive about proposed project benefits in the DEIS.

It would be possible to present actual data from existing wind turbine installations in New York State (Fenner, Wethersfield, and Tug Hill) on electricity generation and consumption and matching data on state power generation from other sources over the same and earlier time periods to see if, in fact, fossil fuel consumption is reduced by the presence of wind generation, and if so, by how much. Since wind generation is erratic, it would be useful to know which alternative sources (fossil fuel vs. nuclear vs. hydro) are dialed down when wind plants are producing. The strength of this analysis could be enhanced by similar information from the states of Vermont, Pennsylvania, and West Virginia, where there are also wind generation facilities in operation. Independent analysts have difficulty gaining access to these figures, perhaps because the data are not favorable to the wind industry.

2. General quality of the DEIS

The Noble Environmental DEIS is a document remarkably naïve of useful data. Data there is, or at least lists of information and tables of numbers which were measured in some way, but the measurements and numbers stop short of demonstrating anything meaningful, even when comparisons are made. Ecology and Environment, Inc. has created for Noble Environmental a soothing, pleasing, and mind-numbing document whose conclusions, section after section, are unsupported assertions of a most vague nature. Problems are masked by inadequate data gathering or presentation. There is no interest in realistic solutions even when problems are documented. The document relies heavily on the unspoken assumption that our presumption is that the project has no environmental impact. If this is the case, inadequate data leads us back to the conclusion that the project has no environmental impact, because the presumption, or null hypothesis as it is called in science, has not been disproven. In reality our presumption in requiring a study of environmental impact is that the impact is significant, and the burden of proof rests with Noble Environmental and its contractor, Ecology and Environment, to demonstrate that the project's environmental impact is sufficiently low relative to the social and economic benefits to be gained. If the data is inadequate or not pertinent to the problem at hand, then our presumption of significant environmental impact has not been disproven.

It is hardly surprising that the creators of this document lack commitment to a scientific approach or to environmental protection, however, given the website description of what Ecology and Environment offers its clients:

"The right environmental permitting strategy can mean the difference between spinning assets and a multi-million dollar write-off. E & E provides strategic environmental permitting approaches to get you the permits you need ahead of schedule and with the operational flexibility you need. From site selection and planning through construction, startup and long-term compliance, E & E's nationwide team specializes in environmental consulting services. We get the approvals you need to get your project on-line ahead of the competition."
(<http://www.ene.com/services/power.asp>)

This approach is not the intent of SEQRA.

The graphic of a wind turbine presented in several locations in the DEIS (Figure 1-3, for example) is deceptive because it does not represent rotor size accurately relative to the height of the tower. Hub height is marked as 80 m, while rotor diameter, marked as 77 m, is represented graphically by a diameter only 59% of what it should be to be proportional to the hub height. Thus the rotor, whose blade reaches essentially half-way down the tower (77 m being approximately equal to 80 m), is represented graphically as a little pinwheel in this diagram. Little jagged lines are added on either side of the tower base to further the illusion that the tower is even taller compared to the rotor size. This diagram is reproduced in the Avian Risk Assessment to misrepresent the rotor-swept area, a critical concept with regard to avian impacts.

3. Safety from lightning, fires, falling turbines, dislocated pieces of turbine, or ice throw.

In section 2.29.1 and 2.29.3, the DEIS fails to acknowledge that none of the fire departments it names has the capability to fight fires in turbine nacelles (generator and gear box) 265 ft. above the ground. Turbine nacelles contain significant amounts of lubricants and hydraulic fluids. Fires may be started by lightning or brake malfunction. A fire may leave wind turbine controls malfunctioning until the equipment in the nacelle is repaired or replaced, making it more susceptible to accidents.

The Clinton Wind Energy Facilities Ordinance allows wind turbines to be erected 1000 ft from Rt. 11, 500 ft. from other roads, 587 ft. (1½ times the total height) from buildings or above-ground utilities, and 1200 ft. from off-site homes. None of these distances are safe with regard to projectiles thrown from spinning 126 ft. turbine blades 390 ft. in the air, such as ice or pieces of blade, which can travel over 1600 ft. In Germany in 2003, in high storm winds, brakes on a wind turbine failed and the blades spun out of control. A blade struck the tower and the entire nacelle flew off the tower. The blades and other parts landed as far as 1650 ft (0.31 mile) from the base of the tower.⁴ This was an "upwind," three-bladed, industrial-sized turbines like those in the Project; "downwind" turbines have not been built since the 1980's. This distance is nearly identical to calculations of ice throw from turbines with 100 ft. blades rotating 20 times per minute (1680 ft) made by a Rutgers University physics professor.⁵

The "Health and Safety Plan" in section 2.29.2 and Appendix P is an exercise in vagueness and promise, without substance, as is "Fire Safety Planning" in 2.29.3. "Ice shed" in section 2.29.5 does not provide for adequate protection for cars driving past turbines 500 ft. away. "Generally," this paragraph reads, "ice buildup slows a turbine's rotation and will be sensed by the turbine's control system, causing the turbine to shut down" (DEIS p. 2-205). "Generally" is not good enough, nor is reliance on a mechanical system without the back-up of adequate setback. There are no plans or preventative measures for lightning strikes or other significant accidents. The most important preventive measure, adequate setback, has not been taken.

Both these considerations – the problems with fire-fighting and the possibilities for projectile throw – were raised with the Clinton Town Board before the Wind Energy Facilities Ordinance was passed. The board had the knowledge they needed to build safer setbacks into the ordinance but failed to do so.

Wind turbines themselves cause irregularities in the power supply as wind speed changes, including power surges as the wind gusts. Residents living near a new wind turbine installation in Meyersdale, PA, which came on line in December 2003, have had to replace stove elements and small appliances due to power surges which started at that time. Residents of Lincoln Township, WI, near a wind installation noticed an increase in lightning strikes in their area after the turbines went on-line in June 1999. Two computers protected by surge protectors and a TV set, all in different houses, were simultaneously "fried" one evening when lightning struck a nearby wind turbine tower.⁶

The DEIS does not discuss lightning precautions or data on lightning strikes from other installations. A search on the word "lightning" yields one hit, in Appendix P, with regard to performing a "risk analysis" and developing a safety plan sometime in the future. The time, however, is now, before permits are issued to allow construction.

4. Seismic activity

DEIS Section 2.1.3, in full:

"According to the USGS, which maintains records extending back to 1638 [sic], two significant earthquake epicenters (magnitude 5.0 or greater) have been recorded in the region. The Project Site is located within a low to moderately active seismic region. One magnitude 5.8 quake occurred in the Massena, New York area in 1944 and one quake with magnitude between 5.0 and 5.9 occurred South of

⁴ See photos at http://www.phase.com/wp/wind_turbine_photos.

⁵ Personal communication, Prof. Terry Matilsky, Dept. of Physics and Astronomy, Rutgers Univ., Piscataway, NJ.

⁶ Bitzner-Mackin, E. 2003. "Excerpts from the final report of the Township of Lincoln Wind Turbine Moratorium Committee." 12-4-03.

Montreal, Quebec in 1877. Both areas are located between 50 and 100 miles from the Project Site. However, no earthquake epicenters with a magnitude of 6.0 or greater have been recorded within 100 miles (U.S. Geological Survey 2006). In addition, no significant tectonic faults have been mapped in Clinton County, and there are no known active faults (i.e., younger than 1.6 million years) in this region (USGS 2002)" (DEIS p. 2-2).

DEIS Section 2.2.3:

"As described in Section 2.1.3, the USGS states that one significant earthquake epicenter (magnitude 5.2) has been recorded within 50 miles of the Project Site and that the Project Site is not located within an active seismic region (U.S. Geological Survey 2001). No significant tectonic faults have been mapped in Clinton County, and there are no known active faults (i.e., younger than 1.6 million years) in this region (U.S. Geological Survey 2002)" (DEIS p. 2-7).

The DEIS preparers cannot even figure out what they themselves are saying in these two contradictory paragraphs and they did not do their homework.

An earthquake of magnitude 5.1 according to the USGS and 5.5 according to the Canadian Geological Survey with an epicenter 15 miles southwest of Plattsburgh occurred on April 20, 2002, at latitude 44.51 and longitude -73.66, 33 miles from the proposed project site. This earthquake was felt all over New York, New England (to Maine), and down to Maryland. Clinton and Essex Counties were declared federal disaster areas due to \$4.06 million worth of damage to roads, buildings, and wells.⁷

Dr. Frank Revetta, professor of earth science and geophysics at SUNY Potsdam and director of the Potsdam Seismic Network, states, "There is an east-west trending gravity high north of the Adirondacks in northern New York [which] correlates with a belt of earthquakes of shallow depth (<18 km). This is the most seismically active area in New York State."⁸

Small quakes of less than magnitude 4 are frequent in the region, including a 3.3 earthquake in Plattsburgh on 5/24/02, two 3.0 earthquakes with epicenters close to that of the larger 4/02 earthquake on 6/25/02 and 12/25/02, a 3.5 earthquake centered in Owl's Head on 4/8/03, and a 2.5 earthquake 3 miles west of the village of Malone on 3/3/05. An earthquake with magnitude 3.7 (4.1 according to the Canadian Geological Survey) occurred on January 9, 2006, just north of the Canadian border 5 miles from the village of Churubusco, NY, the Project location, 12 miles from Noble Environmental's Ellenburg Project, and 15 miles from Altona. "There is a belt of earthquakes that extends from the Adirondacks into Western Quebec." Professor Revetta said to the Plattsburgh Press-Republican. "You can expect earthquakes there quite frequently."⁹

It is unclear whether Noble Environmental's omission of this publicly available information was accidental and careless or deliberate and deceptive, but with regard to public safety neither type of oversight is acceptable. The proposed wind turbines are nearly 400 ft. tall. They are slender columns of tubular steel with a 60-ton nacelle and hub of the 40-ton propeller at 265 ft. The DEIS contains no data on the stability of industrial wind turbines in the presence of earthquakes despite a significant quake

⁷ Reports on North Country earthquakes from the archives of the *Plattsburgh Press-Republican*; "Northeast of US quivers in rare quake," *CNN.COM*, April 20, 2002; Angus McCusker & Frank A. ⁸ Presented March 15, 2005, at the 40th Annual Meeting of the Geological Society of America. Abstracts and Programs, vol 37, no. 1, p. 58.

⁹ ² *Plattsburgh Press-Republican*, 1-10-06. The distances given from Chateaugay and Altona were triangulated to a unique point north of the international border and the distance to Churubusco and Ellenburg Center measured.

occurring 33 miles from the Clinton Project site four years ago and frequent smaller quakes as close as 5 miles away. A 500-587 ft. setback is not adequate to protect the public or leaseholders from harm should a structure of this weight, nearly 400 ft. tall, fall over. For reasons of public safety the setbacks specified in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances must be revised. Construction cannot be permitted under these conditions.

5. Noise and Noise-related Health Issues

The noise standards adopted in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances are wind turbine "industry standards." As such they make things easier on the operators of wind turbines by allowing more noise, but they do not comply with community noise standards promulgated by non-industry agencies such as the NYS DEC¹⁰ or the World Health Organization.¹¹

Compliance with NYS DEC noise standards (increasing the noise level no more than 6 dB over ambient) is anticipated to be almost non-existent near the Ellenburg Project, but noise was not modeled in this way for the Clinton Project: "Sound pressure increases of more than 6 dBA over existing conditions may occur at some on and off-site residences" (DEIS, Appendix H, p. 3-7). This information is discussed only with regard to the fact that legally there does not need to be compliance with this standard because NYS DEC is not the lead agency. There is no plan to mitigate these noise effects. This represents a significant alteration in noise levels judged by state agency (DEC) standards and a significant change in community character, quietness being an important part the community character which leads people to build and live in rural areas.

In Lincoln Township, WI, a University of Wisconsin survey of residents near a 22 turbine installation in 2001, 2 years after construction, documented that 44% of residents 800 ft to ¼ mile from the turbines found noise to be a problem in their households, 52% ¼ to ½ mile away, 32% ½ to 1 mile away, and 4% 1 to 2 miles away. Under certain conditions the turbines could be heard up to 2 miles away.¹² These numbers correspond well to measurements made by Dr. GP van den Berg of the University of Groningen in the Netherlands near a more recent 30 MW, 17 wind turbine installation on the Dutch-German border, where residents living 500 m (1640 ft. or 0.31 mile) and more from the turbines were reacting strongly to the noise, and residents up to 1900 m (1.2 miles) away expressed annoyance.¹³

In a 2005 survey of 200 adult residents within ¼ mile of the French St. Crepin Windfarm, 83% responded. Of these, 27% considered the noise to be intolerable at night, 58% considered the noise to be disturbing, and 10% considered the noise to be disturbing by day. This is only a 6 turbine, 9 MW installation.¹⁴

Dr. van den Berg has now published his research as a book (his dissertation) which is available on-line at <http://dissertations.ub.rug.nl/faculties/science/2006/g.p.van.den.berg/>. Introductory and concluding chapters are reproduced in the accompanying material. His work focuses on figuring out why noise from wind turbines carries so much farther than expected and on developing new acoustic models based on known properties of the atmosphere to improve the current poor accuracy of acoustic modeling in predicting how loudly and how far noise will carry from wind turbines. The introductory chapter provides an engaging, readable description of both the scientific and political aspects of the debate about wind turbine noise. Van den Berg's research also points to design features which could be incorporated into newer turbines which would both improve their efficiency and reduce the annoying types of noise they make.¹⁵

The audible noise produced by wind turbines has a thumping, pulsing character, especially at night, when it is louder. The noise is louder at night because of the contrast between the still, cool air at ground level and the steady stream of wind at the level of the turbine hubs, known as a "stable atmosphere" in which there is little vertical movement of air.¹⁶ This nighttime noise travels long distances. It has been documented to be disturbing to residents 1.2 miles away from wind turbines in regular rolling terrain,¹⁷ and 1.5 miles away in Appalachian valleys.¹⁸ Van den Berg documents how mountainous terrain can either lessen or increase the effect of a stable atmosphere in allowing sound to travel further.

At night, the WHO recommends, the level of continuous noise at the outside a dwelling should be 45 dB or less, and inside, 30 dB or less. The wind turbine noise at levels permitted by the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances are in the range of decibel levels which disturb sleep, even if permitted noise levels are not surpassed. Higher levels of noise disturb sleep and produce a host of effects on health, well-being, and productivity.¹⁹ These and other health effects of excessive community noise are documented in the WHO report with reference to scientific and medical literature. These include:

- For people to understand each other easily when talking, environmental noise levels should be 35 dB or less. For vulnerable groups (hearing impaired, elderly, children in the process of reading and language acquisition, foreign language speakers, and children with developmental disabilities) even lower background levels are needed. When noise interferes with speech comprehension, problems with concentration, fatigue, uncertainty, lack of self-confidence, irritation, misunderstandings, decreased work capacity, problems in human relations, and a number of stress reactions arise.²⁰
- Effects of noise-induced sleep disturbance include fatigue, depressed mood or well-being, decreased performance, and increased use of sedatives or sleeping pills. Measured physiologic effects of noise during sleep are increased blood pressure and heart rate, changes in breathing pattern, and cardiac arrhythmias.²¹ Certain types of nighttime noise are especially bothersome.

²¹ *Ibid.*, p. 44.

including noise which has impulses rather than being continuous, noise combined with physical vibration, noise with low-frequency components,²² and sources in environments with low ambient background noise.²³ Children, the elderly, and people with preexisting illnesses, especially depression, are especially vulnerable to sleep disturbance.

- Noise has an adverse effect on performance over and above its effects on speech comprehension. The most strongly affected cognitive areas are reading, attention, problem solving, and memory. Children in school are adversely affected by noise, and it is the uncontrollability of noise, rather than its intensity, which is most critical. The effort to tune out the noise comes at the price of increased levels of stress hormones and elevation of resting blood pressure. The adverse effects are larger in children with lower school achievement.²⁴
- What is commonly referred to as noise "annoyance" is in fact a range of negative emotions, documented in people exposed to community noise, including anger, disappointment, dissatisfaction, withdrawal, helplessness, depression, anxiety, distraction, agitation, and exhaustion.²⁵ The percentage of highly annoyed people in a population starts to increase at 42 dB, and the percentage of moderately annoyed at 37 dB.²⁶

Participants in noise studies are selected from the general population and are usually adults. Vulnerable groups of people are underrepresented in studies, and if included, would show stronger effects at lower levels of noise. Vulnerable groups include the elderly, people who are sick or have chronic medical conditions, people with depression or other forms of mental illness, babies and young children in general, children with developmental disabilities, children dealing with complex cognitive tasks such as reading acquisition, and people who are blind or hearing impaired. These people may be less able to cope with the impacts of noise exposure and at greater risk for harmful effects than is documented in studies. Attention needs to be paid to them when developing noise setbacks requirements.

There are additional symptoms reported by neighbors of industrial wind turbine installations. Amanda Harry, MD, a British physician, found near a 16-turbine installation in 2003 that 13 out of 14 people surveyed reported an increase in headaches, and 10 reported sleep problems and anxiety. Other symptoms included migraine, nausea, dizziness, palpitations, stress, and depression.²⁷ Dr. Harry's study is in preparation for publication.

Many individual accounts from across the world support the same set of symptoms (in submitted material and clinical interviews I have performed as part of a study in progress). Based on accounts and interviews, and in discussion with Dr. Harry, I have defined the Wind Turbine Syndrome, a complex of symptoms which start when local turbines go into operation and resolve when the turbines are off or when the person is out of the area. The symptoms include:

²⁷ Milner, C. 2004. "Wind farms make people sick who live up to a mile away." *Sunday Telegraph*, 1-25-04; and personal communication from Dr. Harry.

- Sleep problems: audible noise or physical sensations of pulsation or pressure make it hard to go to sleep and cause frequent awakening.
- Headaches which are increased in frequency or severity.
- Dizziness, unsteadiness, and nausea.
- Exhaustion, anxiety, anger, irritability, and depression.
- Problems with concentration and learning.
- Tinnitus (ringing in the ears).

Not everyone near turbines has these symptoms. This does not mean people are making them up; it means there are differences among people in susceptibility. These differences are known as risk factors. Defining risk factors and the proportion of people who get symptoms is the role of epidemiologic studies, which are in progress.

Chronic sleep disturbance is the most common symptom. Exhaustion, mood problems, and problems with concentration and learning are natural outcomes of poor sleep.

Sensitivity to low frequency noise is a potential risk factor. Some people sense low-frequency noise as pressure in the ears rather than heard as sound, or experience a feeling or vibration in the chest or throat.²⁸ Neighbors of industrial wind turbines describe the distressing sensation of having to breathe in sync with a rhythmic pulsation from the turbines which is not necessarily audible, especially at night when trying to sleep.²⁹

Preexisting migraine disorder is emerging as a risk factor for sensitivity to Wind Turbine Syndrome. Migraine is not just a bad headache, but rather a complex neurologic phenomenon that affects the visual, hearing, and balance systems and at times motor control and consciousness itself. Many people with migraine have increased sensitivity to noise and to motion – they get carsick as youngsters, seasick, or very sick on carnival rides. Migraine-associated vertigo (which is the spinning type of dizziness, often with nausea) is a described medical entity. Migraine occurs in 12% of Americans. It is a common, familial, inherited condition.

To keep our balance and feel steady in space, we use three types of input: from our eyes, from stretch receptors in joints and muscles, and from balance organs in the inner ear. At least two of these systems

have to be working, and agreeing, to maintain balance. If the systems don't agree, as in seasickness or vertigo, one feels both ill and unsteady. Wind turbines impinge on this system via the visual disturbance of the moving blades and shadows, and, I hypothesize, by low-frequency air pressure waves impinging on the balance organs of the inner ear.

Older people are may also be at increased risk for effects because of age-related problems with the function of the inner ear or the nerves and parts of the brain which receive signals from the inner ear. Many healthy people age 57 to 91 have such problems: 5% have chronic dizziness, and 24% tinnitus (ringing in the ears).¹⁶ Older people often sleep less soundly and are more likely to have their sleep disturbed by noise.

Dizziness (specifically vertigo) and anxiety are neurologically linked phenomena,¹⁷ so the anxiety and depression seen in association with other symptoms near wind installations are not necessarily an emotional response to symptoms, but may be a neurologically linked response to the balance disturbances themselves. Sleep deprivation also causes anxiety and depression.

Industrial wind turbines produce low-frequency as well as audible noise. Dr. Oguz Soysal, Professor and Chairman of the Dept. of Physics and Engineering at Frostburg State University in Maryland, measured sound levels over half a mile away from the 20 turbine wind farm in Meyersdale, PA, in 2005. Audible (A-weighted) dB (decibel) levels were in the 50-60 range, and audible plus low-frequency (C-weighted) dB were in the 65-70 range.¹⁸ A difference of 10 dB between A and C weighting represents a significant amount of low-frequency noise by World Health Organization standards.¹⁹ Dr. van den Berg measured wind turbine sound spectra 750 m (0.47 mile) from a 17 turbine installation in 2002. His graphs reveal dB levels averaging 68-90 dB in the frequency range less than 10 Hz, and over 60 dB in the 10-100 Hz frequency range.²⁰ Van den Berg states in his dissertation, "I agreed with delegate Jørgen Jakobsen, who presented a paper on low frequency wind turbine noise [Jakobsen 2004], that even though wind turbines did produce an appreciable amount of infrasound, the level was so far below the average human hearing threshold that it could not be a large scale problem"²¹ (emphasis added).

Dr. van den Berg shares the perception common in both the medical and acoustic fields that if you can't hear a noise, it can't affect you, but the world's leading researchers in the health effects of low-frequency noise exposure, Nuno Castelo Branco, MD (Head of the Scientific Board, Center for Human Performance, Alverca, Portugal, and Principal Investigator for the Vibroacoustic Disease Project supported by the Portuguese Ministry of Science and Technology) and Mariana Alvez-Pereira (a biomedical engineer at the New University of Lisbon) do not agree.

This international research group, centered in Portugal and including physicians from Poland, Russia, and the United States, has published extensively on the effects of low-frequency noise on parts of the body

other than the ears, particularly on the cardiovascular, pulmonary, and neurologic systems.¹⁶ The research, ongoing since the late 1980's, includes clinical, pathological, and experimental (animal model) investigations. The entity these physicians and PhD's describe, called Vibroacoustic Disease (VAD), includes fibrosis (laying down of additional fibrous thickening in the form of collagen) in the cardiovascular and pulmonary systems and seizures and cognitive changes in the brain. The disease is caused by long-term exposure to low-frequency noise (less than 500 Hz), most of which cannot be heard.

Just as we cannot detect X rays (because our eyes are not sensitive to this frequency) yet can be harmed by them, so we can be harmed by non-audible noise (pressure waves in the air), though our ears are not sensitive to them. The mechanism of this harm is the differing resonance frequencies of different parts of the human body, especially the chest and skull. Air pressure (sound) waves of certain wavelengths resonate inside these walled spaces, setting up vibrations to which the body responds by reinforcing its softer tissues with extra collagen, causing such problems as thickening of the pericardium (membrane inside which the heart beats) and cardiac valves, fibrosis of the lungs, and proliferation of glial (supporting) cells in the brain.

Vibroacoustic disease has been studied mostly in aviation workers (including pilots, flight attendants, and technicians) but is also found in other industries and community settings. One of the researchers, Mariana Alves-Pereira, a biomedical engineer, has recently compared the noise spectrum of an environment known to predispose occupants to VAD – the cockpit of a commercial jetliner – to the noise spectra of other common community settings. She finds that a variety of community settings have the low-frequency noise potential for causing VAD. She has examined noise measurements of industrial wind turbines provided to her by Amanda Harry, MD, and her collaborating acoustician, Dr. Manley in England and found the low frequency noise intensities to be in the range which can cause VAD, especially given prolonged in-home and overnight exposures. Alves-Pereira has also examined graphs of wind turbine sound pressure levels vs. frequency measured by van den Berg and considers the noise intensities at the lower frequencies to be concerning with regard to their potential for causing VAD. She is aware of the symptomatology of the d'Entremont family in Pubnico, Nova Scotia, who had to move out of their home 1000 ft. from a wind turbine, and notes the similarity of their symptoms to those of people with pathologically proven VAD. Part of our research in progress is to provide Alves-Pereira with additional wind turbine noise measurements.

Alves-Pereira has helped clarify how neighbors and town governments should be handling noise measurements related to wind turbines. An A-weighted decibel measurement misses all the low-frequency noise, since A weighting is designed to mimic the frequency response pattern of the human ear and screens out low-frequency noise. Rather than a single measurement of loudness, noise needs to be characterized by measurement of linear (unweighted) decibel levels in 1/3 octave bands across the sound frequency spectrum. Measurements should be taken inside homes, since the longer wavelengths in low-frequency noise resonate within rooms, magnifying their loudness relative to the outside. Low frequency noise also comes through walls with less attenuation than the 15 dB decrease assumed for audible noise.

Noble Environmental's analysis of noise impacts in this DEIS was technically inadequate with regard to current knowledge. Specifically:

¹⁶ Papers submitted are a selection from many: Branco M, and M Alves-Pereira. 2004. "Vibroacoustic disease," *Noise and Health* 6 (23):3-20; Alves-Pereira M. 1999. "Noise-induced extra-aural pathology: A review and commentary," *Aviation, Space, and Environmental Medicine* 70 (3 Pt 2):A7-21; Martinho Pimenta AJ et al. 1999. "Balance disturbances in individuals with vibroacoustic disease," *Aviation, Space, and Environmental Medicine* 70, no. 3, section II:A96-99; Marciniak W, et al. 1999. "Echocardiographic evaluation of 485 aeronautical workers exposed to different noise environments," *Aviation, Space, and Environmental Medicine* 70 (3 Pt 2):A46-53.

- Ambient noise levels were not measured (Appendix H, Section 3.4, p. 3-3). Assumed rural background noise levels are too high, especially for nighttime, the critical time for noise.
- Sound intensity decreases with distance in complex ways depending on the frequency of the sound (low-frequency sound carries further and passes obstructions with less attenuation), the stability of the atmosphere (turbine noise carries further in a stable atmosphere as occurs at night), and the presence of reflective surfaces (increased propagation across open or frozen lakes or in the presence of a temperature inversion providing a reflective atmospheric layer). The discussion of sound propagation on p. 3-3 of Appendix H is oversimplified and allows for underestimation of the distances to which turbine noise is predicted to be propagated.
- Modeling of sound transmission did not look at the worst case scenario of the nighttime stable atmosphere, and thus underestimated the amount of noise likely to occur at various distances from the turbine installation at night, the critical time in terms of disturbance and health effects. Dr. Leventhall, the project acoustics consultant, is aware of these more accurate models of sound propagation from wind turbines but did not require them to be used in the modeling, showing negligence in his function as a technical consultant.
- The statement on p. 3-8, "Nor would use of alternative equipment further reduce sound levels." may apply to equipment which can be purchased right now but not to equipment which may be designed in the near future to vary blade pitch during rotation as recommended by van den Berg to reduce or eliminate the nighttime thumping which develops in stable atmosphere.²⁷ There is a rush to build because the developer stands to make a lot of money, while from the point of view of community sustainability of this type of development it would make sense to wait a few years until equipment which solves the nighttime noise problem is available.
- The measurement of wind turbine noise at Fenner Wind Farm to screen for low frequency noise occurred over a 17 minute period during the day, though van den Berg points out that to eliminate the interference of wind blowing on the microphone (which can confuse the issue of whether there is low frequency noise) it is better to measure at night under conditions of atmospheric stability (little to no wind at ground level, substantial wind at turbine hub height).
- The acoustic weighting network (or lack of a weighting network) used for the Fenner noise sample was not specified
- Dr. Leventhall, the Project consultant, dismisses the low-frequency noise documented in this measurement (note rise in dB level on the left, low-frequency sides of the graphs) as irrelevant for two reasons: 1) Interference due to microphone noise, and 2) below range of human hearing. Point (1) could be corrected by measuring at another time of day/atmospheric condition, and (2) is contradicted by the research on vibroacoustic disease. Dr. Leventhall does not go so far as to say that there is no low-frequency noise, just that it is "not unusual," in which he is accurate. Wind turbines in general produce low-frequency noise,²⁸ which is a problem elsewhere and is likely to be a problem here, too.

In summary, this Project has substantial potential for adverse noise effects on neighboring residents for which adequate studies have not been performed nor realistic mitigation proposed. Noise impact analysis was performed in a superficial fashion ignoring current knowledge so as to bias results in favor of the developers. Realistic mitigation with current technology means adequate setback. The Academy of Medicine of France has recommended a 1.5 km (0.96 mile) setback because of noise and health issues;²⁹ ours should be at least this. Delaying the Project until the technology is available for varying of blade pitch to increase efficiency and decrease noise would also be appropriate.

6. Shadow flicker

When turning with the sun behind them, turbine blades cast moving shadows across the landscape and houses, creating as a strobe effect within houses which can be difficult to block out. Some people lose their balance or become nauseated when they see the movement of shadows or the movement of the huge blades themselves. As with car or sea sickness, such symptoms occur when the three organs of position and movement perception (the inner ear, eyes, and stretch receptors in muscles and joints) do not agree with each other: the eyes perceive movement while the ears and stretch receptors do not. People with a personal or family history of migraine, or migraine-associated phenomena such as car sickness or vertigo, are more susceptible to these effects. The strobe effect also has the potential, like other flashing lights, to trigger seizures in people with epilepsy.

In Lincoln Township, WI, two years after installation of 22 industrial wind turbines, 33% of residents 800 ft to ¼ mile from the turbines found shadows from the blades to be a problem, 40% ¼ to ½ mile away, 18% ½ to 1 mile away, and 3% 1 to 2 miles away.⁴⁰

Eighty-two houses will be subjected to shadow flicker from the Clinton Project (DEIS Appendix G, p. 5-2). Proposed mitigation will mostly require people to stay inside behind their blinds, which are known not to work to keep out the shadow flicker (DEIS Appendix G, p. 5-12). The only realistic form of mitigation is setback, which is inadequate under Clinton municipal law. From the Lincoln Township data, setback of at least one mile is needed.

7. Birds and bats

The federal government is concerned enough about the potential wildlife mortality due to wide scale development of wind turbines that the GAO (Government Accountability Office) issued a lengthy report in September 2005⁴¹ and the National Academy of Sciences commissioned a 20-month study whose period does not end until December 2006:

"The National Academies will establish an expert committee of approximately 14 members to carry out a scientific study of the environmental impacts of wind-energy projects, focusing on the Mid-Atlantic Highlands as a case example. The study will consider adverse and beneficial effects, including impacts on landscapes, viewsheds, wildlife, habitats, water resources, air pollution, greenhouse gases, materials-acquisition costs, and other impacts. Using information from wind-power projects proposed or in place in the Mid-Atlantic Highlands and other regions as appropriate, the committee will develop an analytical framework for evaluating those effects that can inform siting decisions for wind energy projects. The study also will identify major areas of research and development needed to better understand the environmental impacts of wind-energy projects and reduce or mitigate negative environmental effects. The approximate starting date for

⁴⁰ Lincoln Township Wind Turbine Survey, Agricultural Resource Center, University of Wisconsin Extension/Cooperative Extension, May 16, 2001, by David E. Kubas & Crystal Smith. See tables at end of survey. See also Arlin Monfils, Supervisor, Lincoln Town Board, Letter dated 2-1-00 regarding the grim realities of the windpower project to his community.

⁴¹ GAO, September 2005. "Wind power: Impacts on wildlife and government responsibilities for regulating development and protecting wildlife." <http://www.gao.gov/new.items/d05906.pdf>

the project is April 21, 2005. A pre-publication report will be issued at the end of the project in December, 2006.⁴²

I refer below to a letter to Patrick McCarthy at Ecology and Environment from David Stilwell, Field Supervisor, US Fish & Wildlife Service, dated May 13, 2005.⁴³ This letter is appended to the Environmental Assessment Form on the Noble Environmental website at: <http://www.noblepower.com/our-projects/clinton/documents/NFPCClintonSEQR-EAF-C.pdf>. Since Noble Environmental locked its website against copying or printing (despite their avowed commitment to "transparency"), the attached reproduction is reduced in size and blurred but still legible. The original may be viewed on the website.

Under *Recommendations* in the above letter (Stilwell to McCarthy, 5-13-05), the USFWS states, "Pre-construction studies of bats for this location are recommended. These studies should be of sufficient rigor to determine the temporal and spatial distribution of resident and migrating bat and bird species in and adjacent to the project area during various weather conditions (e.g. fog, rain, low cloud ceilings, clear skies, etc.)." Further, "In order to determine the potential collision-hazard for a particular site, and to account for annual variability, the spatial and temporal uses of the project airspace by birds and bats need to be defined during a multi-year period. This can best be accomplished by using remote sensing technology (radar, acoustic, and infrared) to collect data in various spatial and temporal scales (day and night, season to season, and year to year). Traditional sampling protocols (e.g. visual observation and/or mist netting) may be appropriate to supplement the remote sensing work and would likely be necessary to ground truth the data for individual species. Survey techniques are currently evolving and the project sponsor should work closely with this office and the New York State Department of Environmental Conservation (NYSDEC) to develop a draft study design prior to conducting any studies. Survey results should also be submitted to us for review and comment, along with proposed project-specific avoidance and minimization methods to reduce the risk of bat and bird mortality."

Multi-year studies were not done. Results have not been submitted to USFWS for review. Of note, too, is that David Stilwell, Field Supervisor, USFWS, who wrote the above-reference letter to Noble Environmental, strongly criticized the Avian Risk Assessment (ARA) created by the same environmental consultants, Ecology and Environment, Inc., of Lancaster, NY, for the Chautauqua Wind Project in Chautauqua, NY.⁴⁴ Many of the critiques leveled at the Chautauqua ARA apply to the ARA in the DEIS for Ellenburg, Clinton, and Altona. These include the need for multi-year studies of bird and bat migration (because of the variability in migration timing and location with wind and weather patterns noted within years and year to year), the limitations of mobile radar in detecting small migrating birds and bats, and the role in observer effort in getting realistic information even about the presence of particular species, especially the more critical rare species. As for Chautauqua, there is no data in the ARA for Ellenburg, Clinton, and Altona which pertains to population densities or numbers, yet this is the critical information to have if we are going to be able to assess, in future, the effects of large-scale industrial wind power development on bird and bat populations.

I contacted Timothy Sullivan, the biologist at USFWS in Cortland, NY, (607-753-9334) responsible for the Noble projects in Clinton County, on May 30, 2006. He would like to review the ARA for Ellenburg,

⁴² National Academy of Sciences, "Environmental impacts of wind energy projects." Division of Earth and Life Studies, Board on Environmental Studies & Toxicology. <http://www8.nationalacademies.org/cp/projectview.aspx?key=BEST-K-05-01-A>

⁴³ David Stilwell, USFWS Field Supervisor. Letter to Patrick McCarthy dated 5-13-05.

⁴⁴ David Stilwell (signatory) and Timothy Sullivan (biologist), October 12, 2005. "Comments on our review of 2004 Avian Risk Assessment Report. Chautauqua Wind Project."

Clinton, and Altona as his supervisor, David Stilwell, indicated in his letter of May 13, 2005 would be appropriate, but has not had the time to do this given other responsibilities and the many wind projects under development in NYS. The intensity of development right now, in other words, is undermining our governmental oversight procedures. As I am, he is concerned that the cumulative effect of multiple industrial wind power installations in or just above the St. Lawrence River Valley will have a negative impact on migratory birds of a variety of types. Passerine or songbirds are in a general state of population decline related to the cumulative effects of many insults, including habitat destruction, fragmentation, and loss of quality, impacts with buildings, cell towers, power lines, and other tall objects; and cats and cowbirds (predator accessibility related to habitat fragmentation).

With regard to birds, sensitive species in or near the project area include the Bald Eagle (threatened in NYS), Northern Harrier (a large open-country hawk, threatened in NYS), Pied-Billed Grebe (a small waterfowl, threatened in NYS), Sedge Wren (a wetland species, threatened in NYS), Bicknell's Thrush (a rare eastern thrush, imperiled in NYS), and Common Loon (vulnerable in NYS). Other birds common to our area and on the NYS "Species of special concern" list are Cooper's and Sharp-shinned hawks, Northern Goshawk, Osprey, and American Bittern.

The DEIS description of where Snow Geese occur is inaccurate. Snow Geese use farmlands at least as far west as Malone and east to Lake Champlain in a broad front which is expanding year by year. In fact, we are located in the only flyway (and stop-over, for replenishing energy reserves) of the Greater Snow Goose in the world.⁴⁵ Snow geese spend the month of November and most of December here; Canada Geese arrive earlier and disappear about the same time. Geese and other waterfowl use as part of their migratory pathway extensive wetlands along the St. Lawrence River in Quebec. Just over the border from Fort Covington (Franklin County) is the Réserve nationale de faune du lac Saint-François, "created mainly to protect exceptional wetland habitat on the shores of Lac Saint-François that is used by a variety of aquatic and land birds and shelters a number of rare animal and plant species" (website of the Canadian Wildlife Service).

Ground surveys for spring "migratory" birds were done on only May 25 and 26, 2005, though bird migration through our area runs from late March to late May or so; timing and intensity varies year to year. The birds detected were local breeders, but most of the species detected at this time locally are migrant species which winter elsewhere and fall under the Migratory Bird Act. The methodology used – fine-minute detection periods by seeing or hearing – is an adaptation of the Breeding Bird Survey technique which has no applicability in this situation, and serves only to limit, by extreme limitation of observer effort, the numbers of species detected. There is no attempt made to estimate population numbers or density in any way. The similar technique used for the Breeding Bird Surveys in early and late June, 2005, with 3-minute detection periods, is also inadequate to obtain data on population sizes. This technique was developed to have a uniform way to get simple, limited data from disparate untrained observers across the country. It is not a recognized way of estimating bird population densities or numbers (see references⁴⁶ for discussion).

Bat methodology was limited to visual nighttime monitoring in a beam of infrared light and use of bat call detector devices. Very small numbers of bats were detected in the beams. The preparers of the DEIS

discuss how the visual and radar data were not similar, so dissimilar that they considered these two forms of measurement to be "independent," though of course they were not independent since they were measuring the same phenomenon (birds and bats flying overhead) at the same time; the unrelatedness of the data obtained reflects measurement problems, not "independence" of data sets. At any rate, the visual studies do not allow one to calculate the proportion of "targets" in the radar study which were bats and birds because the two sets of measurements were so different they did not seem to reflect the same nightly phenomenon. The call detector devices were mounted on sites in farmland, and allowed identification of four species between the two sites. As for bird migrant studies, limitation of effort limited the numbers of species detected and no data was collected on population densities or numbers.

Discussion of bat impacts does not reflect findings of large bat kills by wind turbines on Appalachian ridges and the correlation of bat kill with a generating vs. non-generating spinning turbine blade.⁴⁷

Comparisons of numbers such as rates of radar target objects picked up at the different wind plant sites surveyed is meaningless without statistical analysis, since even superficial inspection of the data presented in the graphs in the radar monitoring study show wide variability day to day. When data is variable, it is more likely that average values pulled from such data sets do not differ from each other. This is a most basic concept in statistics which is ignored in the data presentation in the ARA. It is also unclear what point the preparers were trying to make in presenting such comparisons.

To provide references and discussion of adequate migratory bird monitoring, the USFWS comment on the Chautauqua Wind Project DEIS is attached. The sites are different but the methodologic inadequacies are the same, produced by the same contractor, Ecology and Environment.⁴⁸

In summary, there has not been adequate oversight of wind power development proposals by USFWS due to the agency being overwhelmed by the number of such proposals in the state, yet such oversight and coordination of bird and bat population issues across broad geographic fronts is badly needed, as recognized by the initiation of two federal level agency studies in the last year which focus on wildlife issues. The current Project needs to be delayed for such review to take place, and to bring the bird and bat studies closer to compliance with USFWS recommendations by having the developers sponsor at least another year of wildlife studies. USFWS oversight to bring the studies methodologically closer to usefulness, in terms of obtaining population data, is recommended.

8. Non-avian wildlife

With regard to terrestrial and aquatic wildlife, information in the DEIS is thin and suggests both incompetence and lack of effort. Habitat and foraging requirements of the White-tailed deer and Black bear are described with mention that suitable habitat occurs within the Project Area, but population estimates are notably lacking. Pre-construction deer and bear population counts by methods well known to wildlife biologists would be appropriate to allow post-construction comparisons. Without this data, the

⁴⁷ Amat, EB, WP Erickson, J Kerns, and J Horn. 2004. ⁴⁸ David Stilwell (signatory) and Timothy Sullivan (biologist), October 12, 2005, "Comments on our review of 2004 Avian Risk Assessment Report, Chautauqua Wind Project "

effects of wind turbine construction on game species cannot be assessed. To my knowledge before and after population comparisons have not been done for other wind turbine projects in New York State or adjacent states, though hunting is a major recreational activity in rural areas and resident accounts from other wind turbine sites report relative scarcity of deer after construction. This project is the second large windplant proposed for NY State, the first being the Tug Hill Project (120 turbines) built last summer. Many additional projects are in the planning stages. Given SEQRA's focus on cumulative effects, I strongly recommend that before further projects go into construction, including this one, that wildlife biologists controlled by NYSDEC obtain two years' worth of population data on significant game species to allow valid post-construction comparisons, and that turbine complexes not be built across a wide area until post-construction data is available for a limited number of sites.

In the DEIS, further discussion of mammals and other vertebrates is relegated to Table 2.9-1, a list by habitat. This table misses even common species such as red squirrel, weasel species, mink, marten, fisher, otter, red fox, coyote, woodchuck, voles, mice, snowshoe hare, etc., which are common in our Adirondack foothills area, showing insufficient care and effort on the part of the preparers of the DEIS. Population data is again lacking. There is no mention of large predators with large home ranges which may include the project area, including cougar which are regularly seen from Altona into St. Lawrence County, including a video of a cougar with a cub filmed in northern Franklin County in 2003. The cougar is a federal endangered species officially considered to be extirpated in NY State, though it does occur and apparently breeds. Other large mammals of which there are reports in the area include bobcat, wolverine, wolf (also a federal endangered species considered extirpated in NY State), and moose. These species are not considered.

Existing research on the effects of wind turbines on wildlife is not mentioned. Lawrence Rabin, Presidential Management Fellow in the US Forest Service R&D in Washington, DC compared the behavior of two groups of California ground squirrels in similar environments, one close to wind turbines and the other not. To be published in a forthcoming issue of Biological Conservation, the study found that squirrels near turbines were more likely to dash back to their burrows when hearing an alarm call and spent more time looking around for predators. A possible reason for the squirrels' increased alertness is their need to compensate for their reduced ability to communicate through sound. Both behaviors can reduce reproductive success by reducing foraging time and increasing energy expenditure, and have the potential to be shared by a number of animal species.⁴⁹

The discussion of the potential impacts of the project on terrestrial wildlife is, like the discussion of wetlands, an account of inevitabilities and minimization without real content, including the failure to acknowledge the significance of potential impacts. Statements such as:

"Although this will result in a local reduction in the amount of available forest habitat, the total acreage is minor in comparison with the overall acreage of forested land located in the Project Area." (DEIS p. 2-107)

ignore the issue of cumulative effect highlighted by SEQRA. The authors conclude soothingly, "Indirect impacts on wildlife will occur as a result of habitat alteration in association with construction and operation of the Project. However, these impacts are not expected to be significant" (DEIS p. 2-108), having presented no population data, no before-and-after wildlife population figures from other sites, nor even demonstrated basic competence in the wildlife field by presenting an accurate mammal list.

9. Wetlands

⁴⁹ "Wind turbines send wildlife diving for cover." *New Scientist*. Issue 2549, May 3, 2006, p. 18.

Ecology and Environment's disregard or perhaps ignorance of ecological principals is apparent throughout the DEIS, starting with the Executive Summary: "The loss of wetlands will be compensated for by the construction of new wetlands in the same watershed" (DEIS p. 2). An engineer or a backhoe operator can construct a wet place but not a wetland: wetlands have to regenerate and during regeneration will not support the same communities of plants, insects, invertebrates, fish, amphibians, birds, and mammals as they did before they were disturbed. The type of wetland which regenerates depends on soil type, siltation properties, water flow, and the presence of beaver, and has a specific time course. These issues are given no consideration.

The sections of the DEIS on wetlands, particularly the Wetland Delineation Report in Appendix D, presents a variety of maps and detailed descriptions of methodology and the vegetation of different wetland areas within the project area, but does nothing significant with the information. The language used minimizes the importance, "functional value," and size of the various wetlands, and tells us soothingly that "Project facilities have been sited to minimize or avoid wetland impacts to the greatest extent practicable, while still being able to meet the Project objectives" (DEIS Appendix D, p. 7-2). We are being told that wetlands are not important. The possibility of siting changes during construction is left open and uncontrolled: "However, until the individual turbine sites are designed and the final grade contours are established, it is not possible to determine the actual extent of wetland impacts within the turbine sites" (DEIS Appendix D, p. 7-4). Mitigation plans are vague: "If avoidance of drainages and swales is not possible, the turbine site will be designed in such a way to allow for the continuation of the surface flow" (DEIS Appendix D, p. 7-5). Adjacent sentences contain conflicting, vague information: "No significant impacts are expected to streams in the Project Area as a result of construction or operation of the Ellenburg Windpark. Potential indirect impacts may result from construction activities, including increased sedimentation and turbidity caused by increased surface runoff from work areas" (DEIS Appendix D, p. 7-7). [References refer to Ellenburg DEIS as this section is missing from the Clinton DEIS on Noble's website.]

The USACE has jurisdiction over all wetlands and waterways in the United States, regardless of size, which are connected hydrologically to a navigable waterway. This could be a marsh connected to a ditch to a stream to a river which eventually flows into the St. Lawrence River or other navigable waterway.

The USACE will not issue permits to place turbines in wetlands, because turbines don't need to be in wetlands and can be placed elsewhere. However, they issue permits (and require permits) for all crossing of waterways and wetlands in their jurisdiction by roads or power lines.

I spoke on May 31, 2006, with Kevin Bruce in the Albany Field Office of the US Army Corps of Engineers, 1 Bond St., Troy, NY 12180, 518-273-7420, fax 518-273-2055.

The USACE has received applications for all three Noble projects. Mr. Bruce said they are early in the process of reviewing the application for the Clinton project, and that review of the Ellenburg and Altona projects has not yet started. He is planning a site meeting in the 3rd week of June for the Clinton project.

Mr. Bruce told me he commonly is asked by project sponsors if they can go ahead and start constructing roads or break ground in areas of dry land not under the jurisdiction of the USACE, before securing permits from the USACE. The USACE generally advises project sponsors not to do this, since the USACE might request changes in the project to avoid wetlands, including by access roads or power lines.

USACE review, which falls under the Clean Water Act and the National Environmental Policy Act, also triggers federal level review under the Fish and Wildlife Coordination Act and the National Historic Preservation Act.

In summary, it appears that extensive federal level review of the three Noble projects is still in the early stages. It would not be appropriate for the town boards, as the lead agencies, to issue building permits without certifying that the appropriate federal review processes have been completed and the required permits obtained, nor for Noble to proceed with construction without required federal permits.

It is not at all clear from the DEIS that state or federal law will be upheld in the Ellenburg Project with regard to wetlands. Because of the vagueness and apparent project dominance of decisions being made with regard to wetlands, on-site NYSDEC and federal (USACE) oversight will be critical to modify turbine placement decisions during the project planning phase, to oversee them (to prevent changes) during the construction phase, and to oversee other mitigation measures.

Re: Comments Regarding the Noble Windpark

Dear Mr. Filion,

I have been asked to contact you regarding the windpark being proposed in your town by Noble Environmental Power. At the outset, I want to say that I believe that the decisions regarding this park are yours and the purpose of my letter is to inform you about our experiences in Madison County, not to convince what is appropriate for your town.

As the Assistant Director for the Madison County Planning Department, I am acquainted with both wind farms in Madison County; one in the Town of Madison and the second in the Town of Fenner. These were the first large-scale wind projects in New York State. Based on several years of experience I believe that the net effect of these projects has been overwhelmingly positive.

Many of the concerns expressed by interested parties have never come to pass. In general the positive impacts they have had on our communities outweigh any negative impact. I believe that our wind farms have been good for the local economy, and that the majority of people who live in these towns are positive about the wind turbines. This positive reaction is best demonstrated in the Town of Fenner where local volunteers and town officials are working to establish a not-for-profit education facility (Fenner Renewable Energy Education (FREE) Center) that will focus on wind and other alternative power sources. You can learn more about this effort by visiting the following website. <http://www.townoffenner.com/freecenterbrochure.pdf>.

It was suggested that I address several topics that are often the source of confusion in discussions about wind power, and so I would like to submit comments about our experience on these issues. I hope that you or others interested in the Noble project will feel free to call me at the numbers listed above to follow up on my comments if you have specific questions.

1. Noise

Many people wonder whether the turbines are noisy. They do make some noise. When the nacelles rotate to face the wind, they do so under power and there is some noise associated with the operation however it is far less noticeable than most everyday noises around a home or business. Unless you are trying to hear it, you probably won't notice it. I recently conducted a tour for a school group and tried to point out the noise being made by a nearby turbine that was moving to catch the wind. Most members of the group couldn't hear the nacelle turning. I am most familiar with the Fenner site and when the wind is blowing enough to operate the turbines, that's what you hear – the wind.

These machines are a major investment and they demand maintenance on a continuous basis to protect the investment and maintain their efficiency. There is an inherent incentive for the owner to continuously maintain the machines. Maintenance crews are on site at the wind farms daily. That maintenance helps to keep the machines running quietly.

2. Wildlife and domestic animals

I know of no negative impact on animals from either wind farm in Madison County. Fenner is farming country. There are dairy farms and other livestock operations in the immediate area of both wind farms and open agricultural land is beneficial for the quality of the wind. Farming in the area has not been negatively impacted by the placement of the turbines and a care was exercised in facility design to preserve the ability to farm efficiently. Access roads and turbine sites have been designed and landscaped to minimize impact on farm fields. Low profile or no ditches allow farm machinery to cross access roads without the need to maneuver equipment and without damaging equipment. I question whether the turbines have had any more impact on wildlife or farming than would a new, single-family home constructed in the rural countryside.

3. Health and safety issues

In the five years that the Madison and Fenner wind farms have been in operation, I know of no health or safety issues associated with them. The Town of Fenner and Enel, the operator of the site, are cooperating on placing locator signs near each turbine and around the site in order to guide public safety responders should there be any need for a response.

The only real question about safety stems not from the turbines or the wind farm but rather from visitors reaction to them. All of the turbines are well off-road on private property. Sightseers, curious about the turbines, occasionally trespass in an attempt to experience the turbines "up close and personal". Fenner and Enel are collaborating to provide a central location where visitors can learn more and have that experience without trespass.

4. Property values and property taxes

There is no evidence at all that the wind turbines have lowered property values in the towns of Madison or Fenner. We have recently received a study of property values at the Fenner site by Ben Hoen at the Bard Center For Environmental Policy, at Bard College (Annandale on Hudson, NY) that suggests that several factors have offset any potential adverse impacts. Those factors are

1. the windmill array fits the landscape
2. windfarming fits this community's sense of place
3. payments balanced any adverse impacts
4. respected landowners/proponents swayed others
5. residents swapped local impacts for global benefits.
6. effects of the windfarms may be more myth than reality.

People still value the quality of life in Fenner because of its rural nature and surroundings. The Town of Fenner has benefited from payments made by the owner of the wind farm. Private land owners with turbines on their property benefit as well from lease payments.

All of the power lines associated with the Fenner and Madison sites are underground and so the visual impact of the project is minimized. The turbines have a commanding and majestic presence. They are far less objectionable than the maze of wires and poles that line our highways and cross our countryside today.

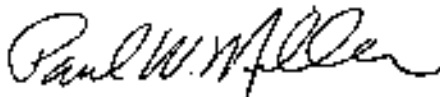

5. Economic development

I feel that both wind farms have been beneficial to the local economy although I can not quantify it. During construction, local operations provided meals and other support to workers. Tourism in the larger geographic area has probably benefited because of visitors coming to see the windmills. The community enjoys the on-going benefit of improvements made to local roads during construction.

Wind farms represent a positive development in society's quest to minimize impact on our planet. Progress is made with each new facility. Clearly there is economic benefit from the effort.

I hope my comments have been helpful to your deliberations. I suggest that those involved in the siting decisions on the Noble application would benefit from a visit to the Fenner site to see the operations there firsthand to form their own opinions. I would be glad to help facilitate the visit. Again, please call if I may be of assistance to you.

Sincerely,

Paul Miller
Assistant Director

* Re: Statement of Support: Noble Clinton Windpark

Statement of New York Interfaith Power and Light

NYIP&L is a not for profit 501(c)(3) faith-based organization that promotes stewardship of God's creation through energy conservation, energy efficiency, and the use of renewable energy. NYIP&L is one of over 30 state based interfaith organizations dedicated to these efforts.

The importance of the Faith Communities across New York and within your community cannot be understated. In 1990 it was estimated¹ that New York had 11,000 congregations with over 11 million adherents. The Faith Communities recognize that the stewardship of creation is a common thread. Some of the many faith-based statements can be seen on our website: www.nyipl.org.

NYIP&L supports renewable energy sources, such as Noble's proposal within the Town of Clinton. The Alliance for Clean Energy New York (ACENY), of which NYIPL is affiliated, can serve as another resource for your town and others interested in renewable energy technologies. See: www.aceny.org. This website highlights how wind energy can provide cleaner air and a more diverse and secure electricity future. NYIPL believe you will find the interviews with local residents and politicians particularly instructive.

The promotion of renewable power such as home grown wind generated power in New York is essential. New York has a tangible renewable resource in wind power that could supply 10% of New York's electrical consumption in the very near future.

The support of the Town of Clinton and others like you is crucial to the growth of renewable energy sources in New York. NYIP&L recognizes the importance (pride) that the members of the faith community have in their ability to choose clean "New

New York
Interfaith Power and Light

York" renewable energy. We commend your efforts and those of the agencies that make this possible.

NYIP&L views the State Environmental Quality Review as another step in the process where New York is making the essential changes required to meet our energy requirements at the least environmental impact. This is a legacy that we can be proud of when we imagine the lives of our children and our children's children. We can hope that our grandchildren will look back and recognize the difference we made..

Finally, NYIP&L commends the Town of Clinton's efforts and those of New York's Environmental and Energy Agencies. These efforts enable us to encourage the faith communities of New York to be good stewards of our environment through the wise use of our energy/financial resources.

Sincerely,

Edward P. Bennett

Michael Filion
7026 Route 11
Churubusco, NY 12923

Dear Mr. Filion:

We are property owners in the Town of Clinton, owning about 1,750 acres along the Canadian Border, north of Clinton Mills Road, reached by Soucia Road. We have signed a contract with Horizon Wind for nine (9) towers on our land.

This letter is to advise you of the very strong support by us of the **Marble River Wind Farm**. While we stand to gain financially from the venture, we would be very much in favor of this even if we were not involved with towers on our land. The benefit to the town and area, the increasing property values and a strong step towards a more secure energy future are all driving reasons.

In our case, should the project be built, not only will the towers on our land generate substantially increased property taxes for Clinton, but our share of the annual income will allow us to continue to improve our lands, giving substantial work to area business people. I hardly think we would be alone. The income derived by the owners of the affected lands should be a great financial boon to the area, positively affecting everyone. Yippee!

I know this has been a difficult process as many people hate change. No doubt some of this controversy has affected you personally and your family. I regret that occurrence. But in my opinion, you have consistently made the right choices in this application. Commencement of the work in 2007 would be a great victory for the Town of Clinton in which you played an important role, in securing a far better financial future at relatively low cost to the area.

I will close by saying that with our large acreage in a very rural location, against the Canadian border, our towers almost unseen by any, the wind potential on our land to be so high that we would welcome far more towers on our land, should the occasion arise.

Thank you all for your hard work in this matter.

Very truly yours,

MARTIN V. LAVIN

Wind Project Comments, Town Board
 Town of Clinton
 7026 Rte. 11
 Churubusco, New York 12923

Dear Town Board Officials:

I would like to enter the following comments into the public record regarding the hearing held at the Ellenburg Town Hall on Wednesday, May 24, 2006 on Noble's Ellenburg Windpark application for a wind energy facility and the accompanying Draft Environmental Impact Statement (DEIS)

On a recent trip to the Tug Hill Windfarm (May, 2006), I observed only one occupied residence within the area of several of the 220' industrial wind turbines. On the other hand, several hundred people reside within the proposed windfarm areas planned for the Towns of Ellenburg and Clinton. These people will be severely negatively impacted by the erection of the proposed 440' wind towers in these townships.

I feel that the industrial wind turbines proposed to be located in the Towns of Ellenburg and Clinton will have a profoundly negative impact on the towns' environments and their citizens:

1) ... I can provide no statistical research supporting or refuting the amount of acceptable decibels of noise which will be produced by the wind turbines - However, I do know that those 220' turbines at the Tug Hill project emit a constant whistling sound and an additional whoosh as the blades pass the tower, a noise which can be equated to a harsh wind in a rainstorm; a loud wind that in this case remains constant.

2) ... I can recommend no acceptable set-back footage for the placement of the proposed wind turbines from area homes - However, I do know that the wind turbines at Tug Hill are scattered, appear random in placement (as they will be in Ellenburg and Clinton), and provide no visual consistency or grouping - many of the Tug Hill turbines are situated away family homes or farms - that will not be the case in Ellenburg and Clinton.

3) ... I can submit no concrete information pertaining to the vertigo produced by the varied speed of the wind turbines' rotating blades - those that are grouped closely together have blades turning at differing and dizzying rates of speed. The shadows produced - especially at dawn and dusk - will tortuously infiltrate nearby homes throughout the day.

4) ... Predictions of the numbers of birds and bats to be killed annually within these windfarm projects is reprehensible - no deaths of wildlife are acceptable - what right have we to predict numbers of deaths of birds and bats (in the hundreds annually!) and casually state that this is an acceptable limit! And is it also acceptable to knowingly alter the migratory paths of wildlife? No!

5) ... Why is it acceptable to disrupt one acre of wetland and reconstruct two acres elsewhere. Sounds good, but what happens to the wildlife within the originally disrupted area? How do they know to relocate??

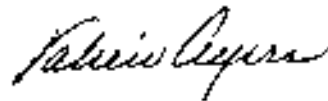

The above issues will certainly negatively impact our environment!

-2-

Finally, and most importantly, no statistical research, propaganda or monetary gifts, leases, or PILOT agreements will compensate for the loss of the beautiful, pristine, natural, countryside which I treasure. The erection of hundreds of 440' industrial wind turbines throughout our gorgeous agrarian countryside will negatively impact our viewshed and our environment in unspeakable ways – ways none of us can yet fully comprehend

No statistical limits of bird and bat kills, noise decibels, vertigo, disruption of emergency cellular service, or tower setbacks are acceptable. My viewshed and environment will be significantly and negatively impacted by the construction of these industrial wind towers! These proposed projects are not only an affront to me but they will be especially detrimental and destructive to our beautiful natural landscape and environment!

Sincerely,

Valerie Ayers

05-31-2006

Dear Mr. Michael Fillion,

I am writing this letter concerning wind turbines. I have land in Clinton County on last nation road.

I want the town board to know that I am against putting up wind turbines. They do not belong in the community. They belong in areas where there are no homes. Besides, my land value will go down. Please put this on record that I am against wind turbines.

I thank you
Yours truly
Alfred Olli

TAX MAP # 21.-1-5

May 23, 2006

Michael Filion
 Supervisor, Town of Clinton
 Town Hall
 23 Smith Street
 Cherusco, NY 12923

Dear Mr. Filion,

Environmental Advocates of New York is pleased to submit the following comments in support of the Noble Clinton Windpark request for approval under SEQRA.

Environmental Advocates of New York is the state's government watchdog, holding lawmakers and agencies accountable for implementing policy that protects natural resources and safeguards public health. For nearly forty years Environmental Advocates has been working to promote responsible and protective energy policies that support renewable energy development, including the implementation of the state Renewable Portfolio Standard (RPS).

In 2004, New York established the RPS with a goal of generating 25% of our electricity from renewable sources by 2013. The RPS is an opportunity for the state to diversify our energy mix and reduce our dependence on polluting energy sources such as oil, gas and coal. Furthermore, achieving these goals will establish New York as a leader in both the use—and the development—of renewable energy.

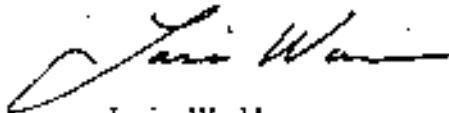

The development of wind power will play an important role in reaching our clean energy goals, and because the technology is ready and available, a large proportion of the new renewable energy developments supported by the RPS are large-scale wind farms. One megawatt of wind energy generates enough electricity to power almost 450 households. If New York's wind capacity were fully realized, wind power could supply clean, renewable electricity to more than four million homes.

Wind is already reducing our dependence on foreign oil and other polluting energy sources. Clean energy and energy efficiency are saving consumers money, and every megawatt of wind power we produce in New York helps displace five tons of sulfur dioxide, two tons of nitrogen oxide, and 1,400 tons of carbon dioxide annually.

However, wind power and the wind farms that supply it are new and unfamiliar, making some New Yorkers concerned about building wind farms in their communities. Although wind power can represent a tremendous economic boost for upstate communities, concerns about noise and scenic impacts are not uncommon, as well as concerns about impacts to birds and other wildlife. Many of these concerns however, are based on out-of-date or inaccurate information. In order for all New Yorkers to embrace the potential of wind energy, communities must work closely with wind power developers to ensure transparency and a shared understanding of how the landscape of their town may or may not be impacted. They also need to be reassured that - across the globe - wind power is a proven technology that is clean, safe, and reliable.

Currently, New York's four operating wind farms are delivering 246mw of electricity to the power grid and providing power for more than 110,000 homes. The experiences during the development stages of these facilities have offered valuable lessons and insight into how to best address concerns and misinformation about the potential impacts of wind power facilities, and can help to guide the future development of wind power in our state. We believe that with a well informed public, proper siting criteria, and an open and fair siting process, significant new wind power generating facilities should be welcomed, providing not only significant environmental benefits, but economic benefits to communities and landowners.

Best regards,

Larisa Washburn
Program Associate
Environmental Advocates of New York
Enclosure (1)

Wind Power

Clean, Safe, Secure
Energy for New York State

New York is putting wind to work.

New York State is home to a tremendous, untapped natural resource—the power of wind. We have the potential to tap more wind power than any other state east of the Mississippi River.

As a proven safe and pollution-free source of energy, wind power safeguards human health and our environment—and is already reducing our dependence on fossil fuels and foreign oil. New York State is currently home to four wind farms that are producing more than 700,000 megawatt hours of power. A coal-fired power plant would have to burn approximately 300,000 tons of coal to generate the equivalent amount of energy.

According to the American Wind Energy Association, wind power is currently serving the energy needs of 2.4 million American households. If New York State's wind capacity were fully realized, wind power could satisfy almost one quarter of our energy needs, supplying clean, renewable electricity to more than four million homes.

Photo: © Environmental Advocates of New York

To a community like this, it's going to be a huge shot in the arm economically. We are a community that needs something. Community-wise and landowner-wise we have had to invest nothing. You know this is just a straight return.

William Burke, Lowville, New York

Wind power is leading the way to a more sustainable
and secure energy future.

Wind power is inexhaustible and non-polluting

Wind power is **clean**. Unlike coal, oil, and gas-fired power plants that threaten our health and contribute to global warming and acid rain, wind farms generate clean, renewable energy without pollution.

More than half of New York's electricity is produced by fossil fuels. As the largest source of industrial air pollution, power plant emissions result in 28,000 asthma attacks, almost 2,000 hospitalizations, and more than 1,200 premature deaths in New York State each year.² Currently, 30 New York counties fail to meet the Environmental Protection Agency's (EPA) minimum air quality standards. In 2000, children living in the New York metro area were twice as likely to be hospitalized for asthma as those from other parts of the country.³

Every megawatt of wind power we produce in New York reduces our reliance on fossil fuels and helps displace five tons of sulfur dioxide, two tons of nitrogen oxide, and 1,367 tons of carbon dioxide annually.⁴

Once complete - with 120 turbines - the Maple Ridge Wind Farm in Lewis County will be the largest wind farm east of the Mississippi and will power more than 100,000 New York homes.

Wind Farms & Property Values

Studies show that wind farms do not have a negative effect on property values, and in many cases, property values have increased within a five mile radius of a wind farm (Renewable Energy Policy Project, 2003, Phoenix Economic Development Group, 2002). For example, tax assessors found that the Fenner wind project had no negative impact on local property values.

Wind power is **safe**. No person has ever been harmed by an operating wind turbine or wind farm. And with continued improvements, wind farms pose minimal risk to wildlife. Across the world, thousands of wind turbines operate safely in both densely populated areas and rural settings.

Wind power is **good for communities**. Wind farms provide economic benefits for families and communities. As development consumes 50,000 acres of farmland each year, wind power can provide the revenue our communities need to preserve their quality of life.⁵

Through land lease agreements and royalty payments, a single wind turbine can provide farmers with \$1,000-\$4,000 per megawatt of power produced each year.⁶ Farmers can also continue to work their land, as animals and crops can be safely located alongside the towers.

Wind farms also benefit communities by creating jobs, promoting tourism, and expanding the local tax base—providing money for schools and services. Payments in lieu of taxes can provide local governments with hundreds of thousands of dollars each year, with low demands on public services.

There are four operating wind farms in New York State, providing electricity for 110,000 homes.

² <http://www.nysenate.gov/education/docs/industry/airpollution>

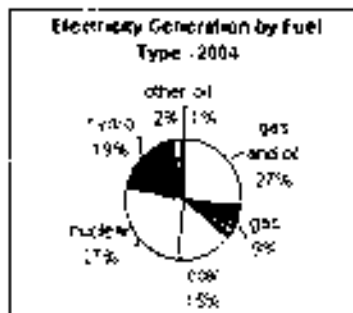

Wind power reduces our dependence on fossil fuels and foreign oil.

One megawatt of New York's wind power generates enough electricity to power almost 450 households.⁷ As the fastest growing electricity source in the world—increasing at a rate of 30% per year⁸—wind energy is just one way that we can reduce our reliance on foreign oil and protect consumers from the price volatility of natural gas. According to the New York Independent System Operator—New York's electric grid operator—more than half of our electricity is currently being produced by fossil fuels.

How Wind Power Works

Modern windmills, or "turbines", convert wind into electricity when their blades rotate, turning a power generator. Built in areas with favorable wind speeds, turbines are grouped into "farms". The electricity produced is sold to electric utilities, power marketers, or government agencies.

In time, wind power will diversify our energy mix, resulting in more affordable energy for consumers. And if New York meets the clean energy goals set by Governor Pataki in 2004, the Public Service Commission predicts that fossil fuel prices will be reduced by at least \$360 million in the next five years, resulting in savings to consumers.

NY Wind Power: Dollars & Sense

- The Fenner, NY wind farm provides approximately \$150,000 each year in lieu of taxes.
- The Madison wind project provides the town with approximately \$30,000 per year.
- Lewis County will collect more than \$8 million in annual payments from the Maple Ridge Wind Farm, due to its location in an Empire Zone.⁹

The Fenner wind farm, on 12 acres of privately owned land, is surrounded by small family farms. The wind farm uses about 1.5% of leased land, remaining land is used for farming. (National Wind Coordinating Committee, 2004)

Wind Power: New Opportunities for New York

New York's Renewable Portfolio Standard (RPS) was created to spur the development of clean energy. The RPS requires that New York increase the energy produced by renewable sources, such as wind power, from 19 to 25% by 2013. With innovations in wind power technology, the state is well positioned to become a leader in the new market for renewable energy. State Comptroller Alan Hevesi recently reported that the RPS could create more than 40,000 new jobs in the manufacturing and energy industries.¹⁰

The RPS is a small investment to create an energy-independent future. The RPS is funded by a small, usage-based surcharge on most electricity sold in New York State. Customer bill impacts are small. Monthly charges that debuted in 2005 ranged from 5 to 15¢.¹¹

Dedicated funds to support wind power also make New York State more attractive to clean energy producers.

Photo courtesy of the U.S. Wind Energy Association

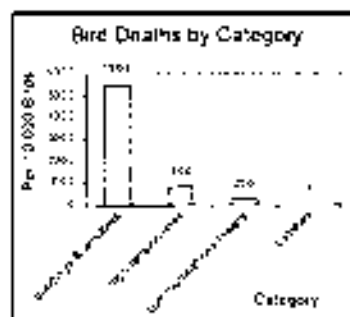

Noise. Today's wind turbines are designed to limit noise. Since the 1970's, modifications have reduced sound levels to 43-45 decibels when measured 750-1,000 feet away, no noisier than a modern kitchen refrigerator. Turbines are usually sited at least 1,000 feet away from homes.¹¹

Shadow Flicker. Careful turbine siting can limit or eliminate shadow flicker. During design, computer models can calculate the shadow zones around turbines during different times of year and times of day. Shadow flicker has occurred when rotating turbine blades create a moving shadow when the sun is low in the sky.¹²

Lighting. The Federal Aviation Administration (FAA) requires that structures over 200 feet be lit with either red or clear strobe lights. Lights are placed at the top of the wind tower. The FAA is working with the wind industry to find the least invasive way to light the towers.¹³

Radio & TV Interference. Wind farms can interfere with radio and TV signals if a turbine is in the "line of sight" between a receiver and the signal source. This problem is easily remedied by improving the receiver's antenna or by installing relays to transmit the signal around the wind farm. Use of satellite or cable television is also an option.¹⁴

Ice Throw. Turbine design has been improved to make sure that ice throw poses minimal risks. If ice builds up on the turbine blades, it slows the turbine's rotation and the imbalance causes the turbine to shut down. In fact, wind farm operators can shut down a turbine if ice accumulates to ensure the blades remain balanced and operate at peak efficiency.¹⁵

Source: Environmental 2007, comparing telegraph poles and bird mortality.

Wildlife. Today's wind farms have relatively low impact on wildlife. Research has shown that the mortality rate for birds from wind turbines is about 2.19 birds per turbine, per year. Communications towers, on the other hand, kill an estimated 28.5 birds per year.¹⁶ Turbines from the 1970's and 80's were designed and located without attention to local wildlife. Since then, concerns have been raised over bird deaths at one of the first wind farms at Altamont Pass in California, and the number of bat deaths at a West Virginia wind farm. Today, risk factors are addressed in turbine siting and design, reducing bird and bat mortality. Environmental groups, federal regulators and the wind industry continue to work together to limit impacts on all wildlife.¹⁷

Wind Power is Reliable. Wind power is producing more than 9,000 megawatts of power each year in the U.S. According to the New York State Energy Research and Development Authority (NYSERDA), New York can generate at least 10% of its power from wind, without destabilizing the power grid— the power can be accommodated by the network already in place.¹⁸

Because of natural variations in demand, and because no type of electricity generating facility operates at 100% capacity 100% of the time, the grid always has more power available than it needs. Therefore, when wind turbines generate electricity, polluting fossil fuel plants reduce their power output, as well as the pollution they generate. The U.S. Department of Energy has determined that adding wind power to the existing grid does not require additional backup power, and that the cost of integrating wind power into the system is negligible—less than 0.2 cents per kilowatt.¹⁹

Town Hall
23 Smith Street
Churubusco, NY 12923

Re: Comments Regarding the Noble Windpark

Dear Mr. Filion,

I have been asked to contact you regarding the windpark being proposed in your town by Noble Environmental Power. At the outset, I want to say that I believe that the decisions regarding this park are yours and the purpose of my letter is to inform you about our experiences in Madison County, not to convince what is appropriate for your town.

As the Assistant Director for the Madison County Planning Department, I am acquainted with both wind farms in Madison County; one in the Town of Madison and the second in the Town of Fenner. These were the first large-scale wind projects in New York State. Based on several years of experience I believe that the net effect of these projects has been overwhelmingly positive.

Many of the concerns expressed by interested parties have never come to pass. In general the positive impacts they have had on our communities outweigh any negative impact. I believe that our wind farms have been good for the local economy, and that the majority of people who live in these towns are positive about the wind turbines. This positive reaction is best demonstrated in the Town of Fenner where local volunteers and town officials are working to establish a not-for-profit education facility (Fenner Renewable Energy Education (FREE) Center) that will focus on wind and other alternative power sources. You can learn more about this effort by visiting the following website. <http://www.townoffenner.com/freecenterbrochure.pdf>.

It was suggested that I address several topics that are often the source of confusion in discussions about wind power, and so I would like to submit comments about our experience on these issues. I hope that you or others interested in the Noble project will feel free to call me at the numbers listed above to follow up on my comments if you have specific questions.

1. Noise

Many people wonder whether the turbines are noisy. They do make some noise. When the nacelles rotate to face the wind, they do so under power and there is some noise associated with the operation however it is far less noticeable than most everyday noises around a home or business. Unless you are trying to hear it, you probably won't notice it. I recently conducted a tour for a school group and tried to point out the noise being made by a nearby turbine that was moving to catch the wind. Most members of the group couldn't hear the nacelle turning. I am most familiar with the Fenner site and when the wind is blowing enough to operate the turbines, that's what you hear - the wind.

These machines are a major investment and they demand maintenance on a continuous basis to protect the investment and maintain their efficiency. There is an inherent incentive for the owner to continuously maintain the machines. Maintenance crews are on site at the wind farms daily. That maintenance helps to keep the machines running quietly.

2. Wildlife and domestic animals

I know of no negative impact on animals from either wind farm in Madison County. Fenner is farming country. There are dairy farms and other livestock operations in the immediate area of both wind farms and open agricultural land is beneficial for the quality of the wind. Farming in the area has not been negatively impacted by the placement of the turbines and a care was exercised in facility design to preserve the ability to farm efficiently. Access roads and turbine sites have been designed and landscaped to minimize impact on farm fields. Low profile or no ditches allow farm machinery to cross access roads without the need to maneuver equipment and without damaging equipment. I question whether the turbines have had any more impact on wildlife or farming than would a new, single-family home constructed in the rural countryside.

3. Health and safety issues

In the five years that the Madison and Fenner wind farms have been in operation, I know of no health or safety issues associated with them. The Town of Fenner and Enel, the operator of the site, are cooperating on placing locator signs near each turbine and around the site in order to guide public safety responders should there be any need for a response.

The only real question about safety stems not from the turbines or the wind farm but rather from visitors reaction to them. All of the turbines are well off-road on private property. Sightseers, curious about the turbines, occasionally trespass in an attempt to experience the turbines "up close and personal". Fenner and Enel are collaborating to provide a central location where visitors can learn more and have that experience without trespass.

4. Property values and property taxes

There is no evidence at all that the wind turbines have lowered property values in the towns of Madison or Fenner. We have recently received a study of property values at the Fenner site by Ben Hoen at the Bard Center For Environmental Policy, at Bard College (Annandale on Hudson, NY) that suggests that several factors have offset any potential adverse impacts. Those factors are

rno tw

P. 03/03

1. the windmill array fits the landscape
2. windfarming fits this community's sense of place
3. payments balanced any adverse impacts
4. respected landowners/proponents swayed others
5. residents swapped local impacts for global benefits.
6. effects of the windfarms may be more myth than reality.

People still value the quality of life in Fenner because of its rural nature and surroundings. The Town of Fenner has benefited from payments made by the owner of the wind farm. Private land owners with turbines on their property benefit as well from lease payments.

All of the power lines associated with the Fenner and Madison sites are underground and so the visual impact of the project is minimized. The turbines have a commanding and majestic presence. They are far less objectionable than the maze of wires and poles that line our highways and cross our countryside today.

3. Economic development

I feel that both wind farms have been beneficial to the local economy although I can not quantify it. During construction, local operations provided meals and other support to workers. Tourism in the larger geographic area has probably benefited because of visitors coming to see the windmills. The community enjoys the on-going benefit of improvements made to local roads during construction.

Wind farms represent a positive development in society's quest to minimize impact on our planet. Progress is made with each new facility. Clearly there is economic benefit from the effort.

I hope my comments have been helpful to your deliberations. I suggest that those involved in the siting decisions on the Noble application would benefit from a visit to the Fenner site to see the operations there firsthand to form their own opinions. I would be glad to help facilitate the visit. Again, please call if I may be of assistance to you.

Sincerely,

Paul Miller

Comments on the Proposed Noble Clinton Windpark

Comments on the Noble Clinton DEIS

Comments by Citizens Campaign for the Environment

Churubusco, New York

May 25, 2006

Thank you for the opportunity to comment. My name is Dereeth Glance, Program Director with Citizens Campaign for the Environment (CCE). Supported by over 80,000 members, CCE is a non-partisan, non-profit advocacy organization working to protect the natural environment and public health. Our work is based on a philosophy of pollution prevention, conservation, and environmental sustainability.

CCE strongly supports increased investment and development of clean, renewable energy and in particular wind energy that has undergone a rigorous environmental review. CCE strongly believes that residents and local governments should make informed decisions on wind power projects based on their individual and specific merits and concerns, with the opportunity review proposals in an open and meaningful process.

As most of us already know, the consumption of energy generated by fossil fuels and nuclear power has serious impacts on human health, wildlife, plants, and the natural environment. The long list of detrimental consequences from our reliance on fossil fuel combustion and nuclear fission include, but are not limited to: acid rain, urban smog, higher rates of lung disease and heart failure, oil spills, contaminated drinking water, rising sea levels, mining impacts, global warming, ecosystem damage, nuclear waste disposal, national and global depletion of finite energy sources, and conflicts over the world's dwindling non-renewable sources. *In particular, increasing concentrations of mercury in fish and wildlife, as well as, the devastating effects of acid rain will continue to significantly impact the environment, economy, and character of the North Country.*

In general CCE strongly supports wind power projects that have undergone rigorous environmental review, for the following reasons:

- **Wind power is emission free.** In contrast to coal, oil, and gas plants, wind facilities do not burn fossil fuels and thus do not produce air pollution. Wind power does not require millions of gallons of water each day for cooling purposes, like fossil fuel and nuclear plants. Wind power is a commercially available, proven clean technology.
- **Wind power is independent of imported fuels.** Once constructed, a wind facility requires no fuel. This reduces our dependence on imported oil and gas, much of which comes from unstable areas of the world. In times of rising and volatile fuel

prices, domestic power production can hedge price fluctuations, increasing energy diversity and security.

- ***Wind power keeps energy dollars at home.*** Buying coal, oil, and gas sends New York dollars out of state and out of the country. In contrast, wind power keeps more of those dollars in-state. Investment in wind power can boost New York's growing renewable technologies industries. Wind facilities will also pay local property taxes or make payments in lieu of taxes.
- ***Wind power helps stabilize energy prices.*** By further diversifying the ways we produce electricity, wind power can help stabilize energy prices. Even a small drop in the demand for natural gas, for example, will bring down the price. This results in more price stability and lower overall energy costs.
- ***Wind power can help farmers and other landowners.*** In New York, many wind facilities will be sited on working farms, with farmers or other landowners paid through long-term leases. For farmers, this can be a new source of income that allows them to farm under and around the turbine. This adds to their property value and can help preserve working farms in New York.
- ***Wind power proposals must be carefully reviewed and sited.*** Renewable energy facilities, like any other form of electric generation, must go through a meaningful environmental review process and be carefully sited. Proposed wind facilities are subject to New York's State Environmental Quality Review Act (SEQR), under which government decision-makers study a wide range of potential economic, environmental, and aesthetic impacts, develop any necessary mitigation measures and provide opportunities for public input. Furthermore, the potential impacts of wind turbines, as currently designed, on public health and wildlife species should be compared to the public health, pollution and ecosystem impacts of traditional fossil fuel generation. In this way, the impacts can be put into a meaningful perspective.

Specific comments on the Noble Clinton Windpark

Many individuals may be unfamiliar with modern wind turbines. New York State currently generates electricity from wind power from wind farms in the Towns of Madison, Fenner, and Weathersfield. Maple Ridge, in St. Lawrence county is the largest wind farm in the east.

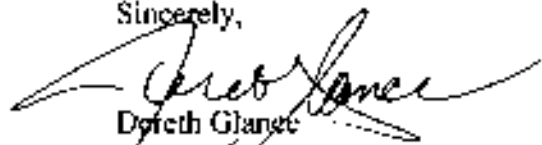

According to the Draft Environmental Impact Statement (DEIS), the Noble Clinton Windpark is a 68 turbine (102 MW) wind energy generating facility or windpark proposed for the town of Clinton, in Clinton County New York. The project will construct 16 miles of access roads, an electrical collection system, and a new substation to ensure the energy generated is safely and efficiently delivered to the grid. The project will effect less than 100 acres, it will disturb 5.8 acres of wetlands and permanently impact 2.75 acres. Impacts to wildlife, including birds and bats will not be biologically significant. Based on mortality rates at other wind facilities in the U.S., the DEIS estimates that 150 individual different bird species birds and zero (0) to 293 individual different species of bats could be killed per year. The project is expected to have no to minimal impacts to groundwater.

CCF believes that the Clinton Windpark positive benefits the environment, local rural economy, and public health. Over the 20 years, the Clinton Windpark is expected to reduce precursors to acid rain, Nitrogen Oxide (NOx) and Sulfur Dioxide, 4,675 and 9,583 tons, respectively. Additionally over 3.0 million tons of Carbon Dioxide (CO2), the chief green house gas contributing to global climate change (global warming) will be displaced as a result of this clean energy project.

In closing, CCF appreciates the opportunity to discuss our perspective with the residents of Clinton. Wind power offers innumerable environmental and economic benefits to the local community, the region, our state, and the nation as a whole. Deciding to host a wind farm in your community is a big decision. It is one that must be made considering all the facts and inclusive of all points of view. There are issues, such as aesthetics, that we must agree to disagree on. Many find these sleek turbines to be examples of "kinetic art," that hold the promise of a better future for our children. And just like other examples of art, there are those that disagree. These perspectives, while both valid, should not be the sole determining factor of whether your community decides to host a wind farm.

Thank you for the opportunity to comment.

Sincerely,

Dorothy Glanec

May 2006

Overview and Summary

In just five years from 2000-2005, wind energy has become a significant resource on many electric utility systems, with over 50,000 MW of nameplate capacity installed worldwide at the end of 2005. Wind energy is now "utility scale" and can affect utility system planning and operations for both generation and transmission. The utility industry in general, and transmission system operators in particular, are beginning to take note. At the end of 2005, the Power Engineering Society (PES) of the Institute of Electrical and Electronic Engineers (IEEE) published a special issue of its *Power & Energy Magazine* (Volume 3, Number 6, November/December 2005) focused on integrating wind into the power system. This document provides a brief summary of many of the salient points from that special issue about the current state of knowledge regarding utility wind integration issues. It does not support or recommend any particular course of action or advocate any particular policy or position on the part of the cooperating organizations.

The discussion below focuses on wind's impacts on the operating costs of the non-wind portion of the power system and on wind's impacts on the electrical integrity of the system. These impacts should be viewed in the context of wind's *total* impact on reliable system operation and electricity costs to consumers. The case studies summarized in the magazine address early concerns about the impact of wind power's variability and uncertainty on power system reliability and costs. Wind resources have impacts that can be managed through proper plant interconnection, integration, transmission planning, and system and market operations.

On the cost side, at wind penetrations of up to 20% of system peak demand, system operating cost increases arising from wind variability and uncertainty amounted to about 10% or less of the wholesale value of the wind energy.¹ These incremental costs, which can be assigned to wind-power generators, are substantially less than imbalance penalties generally imposed through Open Access Transmission Tariffs under FERC Order No. 888. A variety of means -- such as commercially available wind forecasting and others discussed below -- can be employed to reduce these costs. In many cases, customer payments for electricity can be decreased when wind is added to the system, because the operating-cost increases could be offset by savings from displacing fossil fuel generation.

Further, there is evidence that with new equipment designs and proper plant engineering, system stability in response to a major plant or line outage can actually be improved by the addition of wind generation. Since wind is primarily an energy -- not a capacity -- source, no additional generation needs to be added to provide back-up capability provided that wind capacity is properly discounted in the determination of generation

¹ These conclusions will need to be reexamined as results of higher-wind-penetration studies -- in the range of 25% to 30% of peak balancing-area load -- become available. However, achieving such penetrations is likely to require one or two decades. During that time, other significant changes are likely to occur in both the makeup and the operating strategies of the nation's power systems. Depending on the evolution of public policies, technological capabilities, and utility strategic plans, these changes can be either more or less accommodating to the natural characteristics of wind power plants.

capacity adequacy. However, wind generation penetration may affect the mix and dispatch of other generation on the system over time, since non-wind generation is needed to maintain system reliability when winds are low.

Wind generation will also provide some additional load carrying capability to meet forecasted increases in system demand. This contribution is likely to be up to 40% of a typical project's nameplate rating, depending on local wind characteristics and coincidence with the system load profile. Wind generation may require system operators to carry additional operating reserves. Given the existing uncertainties in load forecasts, the studies indicate that the requirement for additional reserves will likely be modest for broadly distributed wind plants. The actual impact of adding wind generation in different balancing areas can vary depending on local factors. For instance, dealing with large wind output variations and steep ramps over a short period of time could be challenging for smaller balancing areas, depending on the specific situation.

The remainder of this document is divided into four sections: wind plant interconnection, wind plant integration, transmission planning and market operation, and accommodating more wind in the future.

Wind Plant Interconnection

- Wind power plant terminal behavior is different from that of conventional power plants, but can be compatible with existing power systems. With current technology, wind-power plants can be designed to meet industry expectations such as riding through a three-phase fault, supplying reactive power to the system, controlling terminal voltage, and participating in SCADA system operation.
- Increased demands will be placed on wind plant performance in the future. Recent requirements include low voltage ride-through capability, reactive power control, voltage control, output control, and ramp rate control. Future requirements are likely to include post-fault machine response characteristics more similar to those of conventional generators (e.g., inertial response and governor response).
- Better dynamic models of wind turbines and aggregate models of wind plants are needed to perform more accurate studies of transmission planning and system operation.
- In areas with limited penetration, modern wind plants can be added without degrading system performance. System stability studies have shown that modern wind plants equipped with power electronic controls and dynamic voltage support capability can improve system performance by damping power swings and supporting post-fault voltage recovery.
- Because of spatial variations of wind from turbine to turbine in a wind plant -- and to a greater degree from plant to plant -- a sudden loss of all wind power on a system simultaneously due to a loss of wind is not a credible event.

Wind Plant Integration

- Utility planners traditionally view new generation primarily in terms of its capacity to serve peak demand. But wind is primarily an energy resource. Its

primary value lies in its ability to displace energy produced from the combustion of fossil fuels and to serve as a hedge against fuel price risk and future restrictions on emissions.

- The addition of a wind plant to a power system does not require the addition of any backup conventional generation since wind is used primarily as an energy resource. In this case, when the wind is not blowing, the system must rely on existing dispatchable generation to meet the system demand.
- Wind plants provide additional planning reserves to a system, but only to the extent of their capacity value. Capacity for day-to-day reliability purposes must be provided through existing market mechanisms and utility unit commitment processes.
- The capacity value of wind generation is typically up to 40% of nameplate rating, and depends heavily on the correlation between the system load profile and the wind plant output.
- The addition of a wind plant to a power system increases the amount of variability and uncertainty of the net load. This may introduce measurable changes in the amount of operating reserves required for regulation, ramping and load-following. Operating reserves may consist of both spinning and non-spinning reserves. In two major recent studies, the addition of 1,500 MW and 3,300 MW of wind (15% and 10%, respectively, of system peak load) increased regulation requirements by 8 MW and 36 MW, respectively, to maintain the same level of NERC control performance standards.
- Fluctuations in the net load (load minus wind) caused by greater variability and uncertainty introduced by wind plants have been shown to increase system operating costs by up to about \$5/MWh at wind penetration levels up to 20%. The greatest part of this cost is associated with the uncertainty introduced into day-ahead unit commitment due to the uncertainty in day-ahead forecasts of real-time wind energy production.
- The impact of adding wind generation can vary depending on the nature of the dispatchable generating resources available, market and regulatory environment, and characteristics of the wind generation resources as compared to the load. Dealing with large output variations and steep ramps over a short period of time (e.g., within the hour) could be challenging for smaller balancing areas, depending on their specific situation.
- Wind's variability cannot be treated in isolation from the load variability inherent in the system. Because wind and load variability are statistically uncorrelated, the net increase of variability due to the addition of wind is less than the variability of the wind generation alone.
- Commercially available wind forecasting capability can reduce the costs associated with day-ahead uncertainty substantially. In one major study, state-of-the-art forecasting was shown to provide 80% of the benefits that would result from perfect forecasting.
- Implementation of wind-plant-output forecasting in both power market operation and system operations planning in the control room environment is a critical next step in accommodating increasing amounts of wind penetration in power systems

Transmission Planning and Market Operation

- Upgrades or additions to transmission facilities may be needed to access locations with large wind-energy potential. Current transmission planning processes are able to identify solutions to transmission problems, but the time required for implementation of solutions often exceeds wind-plant permitting and construction times by several years.
- Well-functioning hour-ahead and day-ahead markets provide the best means of addressing the variability in wind plant output.
- Energy imbalance charges based on actual costs or market prices provide appropriate incentives for accurate wind forecasting. Since wind plant operators have no control over the wind, penalty charges applied to wind imbalances do not improve system reliability. Market products and tariff instruments should properly allocate actual costs of generation energy imbalance.
- Wind turbine output or ramp rates may need to be curtailed for limited periods of time to meet system reliability requirements economically.
- Consolidation of balancing areas or the use of dynamic scheduling can improve system reliability and reduce the cost of integrating additional wind generation into electric system operation.

Accommodating More Wind in the Future

- Understanding and quantifying the impacts of wind plants on utility systems is a critical first step in identifying and solving problems.
- A number of steps can be taken to improve the ability to integrate increasing amounts of wind capacity on power systems. These include:
 - Improvements in wind-turbine and wind-plant models
 - Improvements in wind-plant operating characteristics
 - Carefully evaluating wind-integration operating impacts
 - Incorporating wind-plant forecasting into utility control-room operations
 - Making better use of physically (in contrast with contractually) available transmission capacity
 - Upgrading and expanding transmission systems
 - Developing well-functioning hour-ahead and day-ahead markets, and expanding access to those markets
 - Adopting market rules and tariff provisions that are more appropriate to weather-driven resources
 - Consolidating balancing areas into larger entities or accessing a larger resource base through the use of dynamic scheduling.

Impacts of Windmill Visibility on Property Values in Madison County, New York
 By Ben Hoen, MS
 Bard Center for Environmental Policy, Bard College, Annandale-on-Hudson, NY 12504
 718-812-7589

With a growing reliance on wind energy to mitigate risks from energy security, air pollution and global warming, a continuance of federal renewable energy tax credits, and a number of state incentive packages, U.S. states are seeing wind energy development grow at an unprecedented rate. Additionally windmill and wind farm sizes are growing larger in order to capture greater efficiencies. Conflicts have occurred between community members and facility developers over expected aesthetic impacts and their corresponding property value impacts. Changes in property values can potentially represent "hidden costs" borne by the community. Tom Grey, of the American Wind Energy Association (AWEA) ranks aesthetics and property values as the "number one" concern of communities considering wind farms. Without proper analysis of this subject and a thorough understanding of effects on communities surrounding existing facilities, upcoming projects will be either needlessly delayed or inappropriately approved. Many opinions exist on the effects of wind development on surrounding property values, but no study to date has empirically analyzed the subject and actually visited the homes in the community to establish the degree of turbine visibility.

This report analyzed property values surrounding a 20 turbine windfarm, constructed in 2001, in Madison County, New York to establish if any effects actually exist, and to set standards for future research. 280 arms-length residential home sales within 5 miles of the windfarm and occurring between 1996 and 2005 were analyzed. A visit to each home was made and an unbiased scoring method was used (see left) to quantify the degree to which each of these homes could see the wind farm, and the distance from each home to the turbines. These and other characteristics obtained from the county assessor records were incorporated into an econometric model to ascertain if the properties' sale prices were uniquely affected by the windmill visibility.

length residential home sales within 5 miles of the windfarm and occurring between 1996 and 2005 were analyzed. A visit to each home was made and an unbiased scoring method was used (see left) to quantify the degree to which each of these homes could see the wind farm, and the distance from each home to the turbines. These and other characteristics obtained from the county assessor records were incorporated into an econometric model to ascertain if the properties' sale prices were uniquely affected by the windmill visibility.

The report finds no measurable effects of windmill visibility on property values (p-value

0.410). This absence of evidence holds even when concentrating on homes within a mile (p-value 0.656) or on those that sold immediately following announcement in 2001 (p value 0.742) (See right).

The report suggests a number of reasons why no effects were found: The windmill array fits the landscape; wind farming fits this community's "sense of place;" the payments the community received "balanced" any adverse impacts; a well respected landowner/proponent swayed others; and possibly residents swapped local impacts for global benefits. Further, the report offers the possibility that effects are more myth than reality citing empirical survey studies conducted in Europe which report resident reaction to wind farms largely to be neither good nor bad, but rather "acceptable", and another study which finds the local wind facility is rarely (< 3.0%) spontaneously mentioned in residents' descriptions of their surroundings.² The author recommends further study of 6 to 10 other sites in the U.S. to ascertain if his results can apply to many of the communities considering wind facilities currently across the county.

ENVIRONMENTAL
ADVOCATES OF NY

Your government watchdog

Comment # 248

May 23, 2006

James McNeil
Supervisor, Town of Ellenburg
Town Hall
P.O. Box 22
Ellenburg Center, NY 12934

Dear Mr. McNeil,

Environmental Advocates of New York is pleased to submit the following comments in support of the Noble Ellenburg Windpark request for approval under SEQRA.

Environmental Advocates of New York is the state's government watchdog, holding lawmakers and agencies accountable for implementing policy that protects natural resources and safeguards public health. For nearly forty years Environmental Advocates has been working to promote responsible and protective energy policies that support renewable energy development, including the implementation of the state Renewable Portfolio Standard (RPS).

In 2004, New York established the RPS with a goal of generating 25% of our electricity from renewable sources by 2013. The RPS is an opportunity for the state to diversify our energy mix and reduce our dependence on polluting energy sources such as oil, gas and coal. Furthermore, achieving these goals will establish New York as a leader in both the use—and the development—of renewable energy.

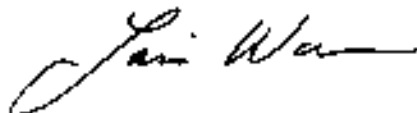

The development of wind power will play an important role in reaching our clean energy goals, and because the technology is ready and available, a large proportion of the new renewable energy developments supported by the RPS are large-scale wind farms. One megawatt of wind energy generates enough electricity to power almost 450 households. If New York's wind capacity were fully realized, wind power could supply clean, renewable electricity to more than four million homes.

Wind is already reducing our dependence on foreign oil and other polluting energy sources. Clean energy and energy efficiency are saving consumers money, and every megawatt of wind power we produce in New York helps displace five tons of sulfur dioxide, two tons of nitrogen oxide, and 1,400 tons of carbon dioxide annually.

However, wind power and the wind farms that supply it are new and unfamiliar, making some New Yorkers concerned about building wind farms in their communities. Although wind power can represent a tremendous economic boost for upstate communities, concerns about noise and scenic impacts are not uncommon, as well as concerns about impacts to birds and other wildlife. Many of these concerns however, are based on out-of-date or inaccurate information. In order for all New Yorkers to embrace the potential of wind energy, communities must work closely with wind power developers to ensure transparency and a shared understanding of how the landscape of their town may or may not be impacted. They also need to be reassured that - across the globe - wind power is a proven technology that is clean, safe, and reliable.

Currently, New York's four operating wind farms are delivering 246mw of electricity to the power grid and providing power for more than 110,000 homes. The experiences during the development stages of these facilities have offered valuable lessons and insight into how to best address concerns and misinformation about the potential impacts of wind power facilities, and can help to guide the future development of wind power in our state. We believe that with a well informed public, proper siting criteria, and an open and fair siting process, significant new wind power generating facilities should be welcomed, providing not only significant environmental benefits, but economic benefits to communities and landowners.

Best regards,

Larisa Washburn
Program Associate
Environmental Advocates of New York

Wind Power

Clean, Safe, Secure
Energy for New York State

New York is putting wind to work.

New York State is home to a tremendous, untapped natural resource—the power of wind. We have the potential to tap more wind power than any other state east of the Mississippi River.

As a proven safe and pollution-free source of energy, wind power safeguards human health and our environment—and is already reducing our dependence on fossil fuels and foreign oil. New York State is currently home to four wind farms that are producing more than 700,000 megawatt hours of power. A coal-fired power plant would have to burn approximately 300,000 tons of coal to generate the equivalent amount of energy.¹

According to the American Wind Energy Association, wind power is currently serving the energy needs of 2.4 million American households. If New York State's wind capacity were fully realized, wind power could satisfy almost one quarter of our energy needs, supplying clean, renewable electricity to more than four million homes.

Photo courtesy of the New York State Energy Research and Development Authority

To a community like this, it's going to be a huge shot in the arm economically. We are a community that needs something. Community-wise and landowner-wise we have had to invest nothing. You know this is just a straight return.

William Burke, Lowville, New York

Wind power is leading the way to a more sustainable
and secure energy future.

Wind power is inexhaustible and nonpolluting.

Wind power is clean. Unlike coal, oil, and gas-fired power plants that threaten our health and contribute to global warming and acid rain, wind farms generate clean, renewable energy without pollution.

More than half of New York's electricity is produced by fossil fuels. As the largest source of industrial air pollution, power plant emissions result in 28,000 asthma attacks, almost 2,000 hospitalizations, and more than 1,200 premature deaths in New York State each year.¹ Currently, 30 New York counties fail to meet the Environmental Protection Agency's (EPA) minimum air quality standards. In 2000, children living in the New York metro area were twice as likely to be hospitalized for asthma as those from other parts of the country.²

Every megawatt of wind power we produce in New York reduces our reliance on fossil fuels and helps displace five tons of sulfur dioxide, two tons of nitrogen oxide, and 1,367 tons of carbon dioxide annually.³

Once complete with 129 turbines— the Maple Ridge Wind Farm in Lewis County will be the largest wind farm east of the Mississippi and will power more than 160,000 New York homes.

Wind Farms & Property Values

Studies show that wind farms do not have a negative effect on property values, and in many cases, property values have increased within a five mile radius of a wind farm (Renewable Energy Policy Project, 2003; Phoenix Economic Development Group, 2002). For example, tax assessors found that the Fenner wind project had no negative impact on local property values.

Wind power is safe. No person has ever been harmed by an operating wind turbine or wind farm. And with continued improvements, wind farms pose minimal risk to wildlife. Across the world, thousands of wind turbines operate safely in both densely populated areas and rural settings.

Wind power is good for communities. Wind farms provide economic benefits for families and communities. As development consumes 50,000 acres of farmland each year, wind power can provide the revenue our communities need to preserve their quality of life.⁴

Through land lease agreements and royalty payments, a single wind turbine can provide farmers with \$1,000-\$4,000 per megawatt of power produced each year.⁵ Farmers can also continue to work their land, as animals and crops can be safely located alongside the towers.

Wind farms also benefit communities by creating jobs, promoting tourism, and expanding the local tax base—providing money for schools and services. Payments in lieu of taxes can provide local governments with hundreds of thousands of dollars each year, with low demands on public services.

There are four operating wind farms in New York State, providing electricity for 110,000 homes.

1. EPA, "Air Quality Criteria for Particulate Matter," EPA-452/P-03-001a, 2003.

One megawatt of New York's wind power generates enough electricity to power almost 450 households.⁷ As the fastest growing electricity source in the world—increasing at a rate of 30% per year⁸—wind energy is just one way that we can reduce our reliance on foreign oil and protect consumers from the price volatility of natural gas. According to the New York Independent System Operator—New York's electric grid operator—more than half of our electricity is currently being produced by fossil fuels.

How Wind Power Works
Modern windmills, or "turbines", convert wind into electricity when their blades rotate, turning a power generator. Built in areas with favorable wind speeds, turbines are grouped into "farms". The electricity produced is sold to electric utilities, power marketers, or government agencies.

In time, wind power will diversify our energy mix, resulting in more affordable energy for consumers. And if New York meets the clean energy goals set by Governor Pataki in 2004, the Public Service Commission predicts that fossil fuel prices will be reduced by at least \$360 million in the next five years, resulting in savings to consumers.

NY Wind Power: Dollars & Sense

- The Fenner, NY wind farm provides approximately \$150,000 each year in lieu of taxes.
- The Madison wind project provides the town with approximately \$30,000 per year.
- Lewis County will collect more than \$8 million in annual payments from the Maple Ridge Wind Farm, due to its location in an Empire Zone.⁹

The Fenner wind farm, on 12 acres of privately owned land, is surrounded by small family farms. The wind farm uses about 1.5% of leased land, remaining land is used for farming. (National Wind Coordinating Committee, 2004).

Wind Power: New Opportunities for New York

New York's Renewable Portfolio Standard (RPS) was created to spur the development of clean energy. The RPS requires that New York increase the energy produced by renewable sources, such as wind power, from 19 to 25% by 2013. With innovations in wind power technology, the state is well positioned to become a leader in the new market for renewable energy. State Comptroller Alan Hevesi recently reported that the RPS could create more than 40,000 new jobs in the manufacturing and energy industries.¹⁰

The RPS is a small investment to create an energy-independent future. The RPS is funded by a small, usage-based surcharge on most electricity sold in New York State. Customer bill impacts are small. Monthly charges that debuted in 2005 ranged from 5 to 15¢.¹¹

Dedicated funds to support wind power also make New York State more attractive to clean energy producers.

The Facts about Wind Power

Noise. Today's wind turbines are designed to limit noise. Since the 1970's, modifications have reduced sound levels to 43-45 decibels when measured 750-1,000 feet away, no noisier than a modern kitchen refrigerator. Turbines are usually sited at least 1,000 feet away from homes.¹⁷

Shadow Flicker. Careful turbine siting can limit or eliminate shadow flicker. During design, computer models can calculate the shadow zones around turbines during different times of year and times of day. Shadow flicker has occurred when rotating turbine blades create a moving shadow when the sun is low in the sky.¹⁸

Lighting. The Federal Aviation Administration (FAA) requires that structures over 200 feet be lit with either red or clear strobe lights. Lights are placed at the top of the wind tower. The FAA is working with the wind industry to find the least invasive way to light the towers.¹⁹

Radio & TV Interference. Wind farms can interfere with radio and TV signals if a turbine is at the "line of sight" between a receiver and the signal source. This problem is easily remedied by improving the receiver's antenna or by installing relays to transmit the signal around the wind farm. Use of satellite or cable television is also an option.²⁰

Ice Throw. Turbine design has been improved to make sure that ice throw poses minimal risks. If ice builds up on the turbine blades, it slows the turbine's rotation and the imbalance causes the turbine to shut down. In fact, wind farm operators can shut down a turbine if ice accumulates to ensure the blades remain balanced and operate at peak efficiency.²¹

Source: Environmental Defense Fund, "Wind Energy: Clean, Safe and Renewable," 12/10/09.

Wildlife. Today's wind farms have relatively low impact on wildlife. Research has shown that the mortality rate for birds from wind turbines is about 2.19 birds per turbine, per year. Communications towers, on the other hand, kill an estimated 28.5 birds per year.²² Turbines from the 1970's and 80's were designed and located without attention to local wildlife. Since then, concerns have been raised over bird deaths at one of the first wind farms at Altamont Pass in California, and the number of bat deaths at a West Virginia wind farm. Today, risk factors are addressed in turbine siting and design, reducing bird and bat mortality. Environmental groups, federal regulators and the wind industry continue to work together to limit impacts on all wildlife.²³

Wind Power is Reliable. Wind power is producing more than 9,000 megawatts of power each year in the U.S. According to the New York State Energy Research and Development Authority (NYSERDA), New York can generate at least 10% of its power from wind, without destabilizing the power grid—the power can be accommodated by the network already in place.²⁴

Because of natural variations in demand, and because no type of electricity generating facility operates at 100% capacity 100% of the time, the grid always has more power available than it needs. Therefore, when wind turbines generate electricity, polluting fossil fuel plants reduce their power output, as well as the pollution they generate. The U.S. Department of Energy has determined that adding wind power to the existing grid does not require additional backup power, and that the cost of integrating wind power into the system is negligible—less than 0.2 cents per kilowatt.²⁵

Dear Town Board Member,

I am writing to each of you to express my support for The Marble River Wind Project. I live in the Central New York community of Sauquoit which is approximately ten miles South of Utica and about ten miles northeast of The Madison Windpower Project. I believe the Madison project was the first modern wind project in New York; being constructed and put into service in 1999 with seven 1.65 megawatt structures.

I am originally from the Ellenburg area having moved to Central NY in 1977 and own land in the Town of Clinton in partnership with my brother and former brother in law. I see the proposed wind project as a huge opportunity for the area for the following reasons:

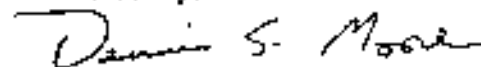

- The project will bring good paying jobs for local residents and revenue to the area before, during and after construction. I recently witnessed the construction boom in the Lowville area last year as workers occupied local hotels and restaurants. Local people were employed and local concrete companies, excavators, contractors all benefited in the construction of The Maple Ridge Project. After the construction phase people and jobs are and will be in place to maintain these facilities.
- The project will decrease the tax burden for local residents as it has in Madison and Lowville areas. I recently spoke with the Business Manager of the Madison Central School District and learned they have partnered with their local project since 1999 receiving payments that have reduced local taxpayer's burden.
- It is an opportunity for the area to assist in this Nation's development of **clean renewable energy**. As you have seen recently by skyrocketing energy prices this nation needs to develop other sources of energy and wean itself from dependence on foreign sources.
- It is an opportunity to teach area children and residents that we can harness a resource that has at times been a curse. My family and I attended the open house held in the fall of 1999 by Pacific Gas and Electric, the Madison Windpower Project developer, at the Madison Central School. Approximately five thousand people attended and were bused to the site on Madison Central School buses to observe the windmills in operation and learn all the facts about them. These seven windmills along with nineteen in Fenner have remained a source of interest and tours to this day.

My experience with the Madison and Maple Ridge Wind Projects makes me question the objections of project opponents. The claims heard from opponents when I

attended local Town Board meetings in Clinton and Ellenburg are not being expressed by local land owners and wind project neighbors in this area.

I appreciate your time and effort and urge you to support this project which will greatly benefit the area!

Sincerely,

A handwritten signature in black ink that reads "Dennis S. Moore". The signature is written in a cursive style with a large, sweeping initial "D".

May 30, 2006

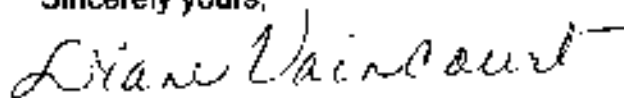

My name is Diane LaBarre Vaincourt, of 7837 Star Road Route 190 Ellenburg Center. I was also born and raised in Ellenburg and have lived here for more than half of my 60 years.

For thirty years I was involved in the petroleum industry. Early on as a bookkeeper and office manager the past eighteen of a company owned and operated by my husband and myself.

An industry so regulated by politicians and lobby groups that we as individuals, communities, etc need to find better ways of producing energy and reduce our reliance on fossil fuels. I believe in wind energy, I want this industry in my town and surrounding areas. The creation of reliable energy, jobs, tax reduction and more are positive benefits. But most of all doing something beneficial for our country and future generations is the key to a responsible person.

I am also very proud of our Town Board and all its members for their effort, research, and their patience with all the multitude of speakers at various procedures. You have shown how efficiently you can work together for the benefit of our town. Thank you very much for being worthy of my vote.

Sincerely yours,

A handwritten signature in cursive script that reads "Diane Vaincourt". The signature is written in black ink and is positioned below the typed name.

* Re: Statement of Support: Noble Ellenburg Windpark

Statement of New York Interfaith Power and Light

NYIP&L is a not for profit 501(c)(3) faith-based organization that promotes stewardship of God's creation through energy conservation, energy efficiency, and the use of renewable energy. NYIP&L is one of over 30 state based interfaith organizations dedicated to these efforts.

The importance of the Faith Communities across New York and within your community cannot be understated. In 1990 it was estimated¹ that New York had 11,000 congregations with over 11 million adherents. The Faith Communities recognize that the stewardship of creation is a common thread. Some of the many faith-based statements can be seen on our website: www.nyipl.org.

NYIP&L supports renewable energy sources, such as Noble's proposal within the Town of Ellenburg. The Alliance for Clean Energy New York (ACENY), of which NYIPL is affiliated, can serve as another resource for your town and others interested in renewable energy technologies. See: www.aceny.org. This website highlights how wind energy can provide cleaner air and a more diverse and secure electricity future. NYIPL believe you will find the interviews with local residents and politicians particularly instructive.

The promotion of renewable power such as home grown wind generated power in New York is essential. New York has a tangible renewable resource in wind power that could supply 10 % of New York's electrical consumption in the very near future.

The support of the Town of Ellenburg and others like you is crucial to the growth of renewable energy sources in New York. NYIP&L recognizes the importance (pride) that the members of the faith community have in their ability to choose clean "New York" renewable energy. We commend your efforts and those of the agencies that make this possible.

New York
Interfaith Power and Light

NYIP&L views the State Environmental Quality Review as another step in the process where New York is making the essential changes required to meet our energy requirements at the least environmental impact. This is a legacy that we can be proud of when we imagine the lives of our children and our children's children. We can hope that our grandchildren will look back and recognize the difference we made..

Finally, NYIP&L commends the Town of Ellenburg's efforts and those of New York's Environmental and Energy Agencies. These efforts enable us to encourage the faith communities of New York to be good stewards of our environmental through the wise use of our energy/financial resources.

Sincerely,

RE: DEIS Setback for Schools

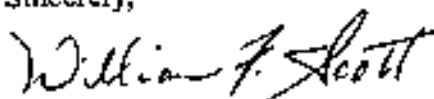

Dear Mr. McNeil:

The Draft Environmental Impact Statement for the Town of Ellenburg fails to provide for a setback of at least 2,500 ft. from the property line of any school, church, hospital or nursing home. Please be advised that this setback is provided in the DEIS for the Town of Clinton.

I respectfully request that the Town of Ellenburg provide at least the equivalent setback as provided to the Town of Clinton for our schools.

Thank you for your attention to this important request.

Sincerely,

William F. Scott
Superintendent of Schools

Daniel Spitzer

June 2, 2006

Dear Town Board Members,

I looked over the DEIS for Noble Windpark and have some very deep concerns over its contents.

To reference a few, I could not find where the 'earthquake' issue was addressed. There need to be special provisions for this type of activity, especially for those who will actually be living in close proximity to the towers. Also, the amount of acreage that will be destroyed is **absurd** and what falls under 'wetland protection' is completely **unacceptable**. I believe the Army Corps of Engineers will be taking a closer look at that particular study.

I suggest you not rush to accept this DEIS. We all know Noble is 'under the gun' to get things rolling but NOT at our community's expense! I am certain there are many more issues that need to be addressed by experts in the field and not solely by those which Noble hired.

Sincerely,

Daryl Lawrence

 Malone, NY 12953
 (518) 483-6481

May 31, 2006

Abstract:

- 1) **Benefits claimed for wind power are inflated by failure to use realistic, published efficiency figures. No evidence is presented to support industry claims that production of wind-generated electricity lessens fossil fuel consumption.**
- 2) **The quality of the DEIS is superficial and presentation is deceptive. The avowed goal of the company which prepared the DEIS is fast permitting, not protection of environment or community.**
- 3) **Safety with regard to turbine fires, lightning strikes, and ice or blade throw is not adequately addressed.**
- 4) **Data on turbine stability in the presence of earthquakes is not presented. The DEIS preparers failed to note an earthquake of magnitude 5.1 which occurred 25 miles from the proposed project area in 2002 and caused \$4 million worth of damage. Setback of 500 ft. from roads and 587 ft. from on-site buildings, as specified in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances, is not adequate to protect the public should one of these slender 400 ft. structures with 100 tons of equipment near the top fall over.**
- 5) **Noise standards adopted in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances do not comply with community noise standards promulgated by non-industry agencies such as the NYS DEC or the World Health Organization, and as such will not protect the public from the health impacts of excessive community noise. Noise modeling did not use up-to-date models of the known distant propagation of annoying noise from wind turbines under conditions of nighttime atmospheric stability. Noble Environmental's acoustics consultant is well aware of these models and was negligent in not requiring their use. While recognizing that wind turbines produce low-frequency noise, the acoustics consultant appears to be ignorant of the medical research literature on the brain, lung, and heart pathology caused by long-term exposure to noise at frequencies too low to be heard.**
- 6) **Shadow flicker produces symptoms of motion sickness in susceptible people and has the potential to trigger seizures in individuals with epilepsy.**

- 7) Bird and bat studies are inadequate with regard to standards communicated by USFWS to Noble with regard to migratory birds, threatened and endangered species, and eagles. No population figures can be derived from the data obtained and presented in the DEIS. Multi-year studies were not performed. There is no adequate baseline created here by which to use this wind turbine installation to study the effects of wind turbines on bird and bat populations.
- 8) The non-avian wildlife section shows incompetence. As in (7), no population data is presented on which to base studies of the effects of wind power development on game species such as deer and bear.
- 9) It is not clear in the DEIS that appropriate state and federal (Army Corps of Engineers) oversight and permitting has taken place with regard to wetlands within the project areas. In fact it has not, according to the responsible Army Corps of Engineers official I spoke to on May 31, 2006, at which point review of the Clinton Project application was in the early stages and review of the Ellenburg and Altona Project applications not yet under way. Permits are required for all activities impinging on any wetland or stream connected ultimately to a navigable waterway. Federal review under the Fish and Wildlife Coordination Act and the National Historic Preservation Act are also required, triggered by projects falling under Army Corps of Engineers jurisdiction.

Introduction:

I am a graduate of Yale (BA 1977, Biology), Princeton (PhD 1985, Population Biology), and Johns Hopkins (MD, 1991). Population Biology is ecology, evolution, and animal behavior. I studied the behavior and ecology of Amazonian birds, spending two years in the field in South America forests. Besides this, I did a year-long (1985-6) post-doctoral fellowship in ornithology at the American Museum of Natural History, NYC. I have lived in this region (Franklin County) of NY State, where I practice behavioral and developmental pediatrics, for nine years. I am familiar with local ecology as well, as a physician, with health and safety issues.

It is "the intention of the Legislature that the protection and enhancement of the environment, human and community resources should be given appropriate weight with social and economic considerations in determining public policy, and that these factors be considered together in reaching decisions on proposed activities" (SEQRA 617.1 Authority, intent, and purpose.). The first issue to be considered here is thus whether there is sufficient social and economic gain anticipated from this project to make it worth the environmental impacts it will have.

SEQRA emphasizes the importance of cumulative impacts from simultaneous or subsequent projects in addition to the specific current project. Industrial wind generating installations are in the planning stages across northern New York State from Cape Vincent to Plattsburgh. The first wave of a large installation has already been built on the high ground east of Lake Ontario (Tug Hill Plateau, Lewis County). The current Noble Environmental applications represent only "Phase 1" in the locations of Ellenburg, Clinton, and Altona. Between Noble Environmental and Marble River, the two companies operating in Franklin and Clinton Counties, 800 or more turbines are currently proposed (data from applications to the New York Independent Systems Operator {NYISO}).¹ The cumulative viewpoint significantly alters how we view issues of land use, agricultural land preservation, community character, and impacts on wildlife. In the Noble Environmental DEIS's, the cumulative viewpoint is limited to their own current projects and

¹ www.nyiso.org. See "NYISO Interconnection Queue," under NYISO Planning, under the Services drop-down menu.

does not consider the wider problem of many hundreds of wind turbines spanning the length of the highlands above the St. Lawrence River Valley from Lake Ontario eastward. Moving further west, turbine installations are also in planning south of Lake Ontario and throughout rural upstate NY.

I will address first the issue of social and economic benefits, and then the following areas in which I have expertise and find Noble Environmental's assessment of environmental risks to be inadequate or faulty: creation of hazards to human health, noise levels, wildlife effects (including game animals and migratory birds), and wetlands.

1. Assertions about the project's public benefit

Noble Environmental makes assertions about the positive effects its product, wind-generated electricity, will have on reduction of emissions from other power plants (DEIS p. 4 and 1-16). These assertions are based on the stated assumption (p. 1-16) that this 81 MW windplant (54 turbines x 1.5 MW per turbine) will indeed deliver 81 MW of electric power to the power grid. This assumption is inflated and deliberately deceptive with regard to the project's public benefits. General Electric, the turbine manufacturer, in a report to the New York State Energy Research and Development Authority (NYSERDA) on March 4, 2005, stated, "Capacity factors of inland wind sites in New York are on the order of 30% of their rated capacity. Their effective capacities, however, are about 10% [of rated capacity], due to both the seasonal and daily patterns of the wind generation being largely 'out of phase' with the NYISO load patterns."² The erratic nature of wind and the impossibility of matching supply to demand with wind-generated power make it the least preferred power source for the Independent Systems Operator (New York State power grid), which does not want the proportion of wind-generated power to approach current goals of the NYS Renewable Portfolio Standard (25% for all renewable sources) because of grid stability issues and because the NYISO's need is for capacity (power generated at the specific time to match needs) not energy (power generated at other times) (testimony presented at the RPS Hearing of the Energy Committee of the NYS Assembly, March 7, 2006). NYSERDA further states that wind power can produce, at most, 1.7% of NY State's electricity needs.³ Noble Environmental is aware of these limitations and writes with intent to deceive about proposed project benefits in the DEIS.

It would be possible to present actual data from existing wind turbine installations in New York State (Fenner, Wethersfield, and Tug Hill) on electricity generation and consumption and matching data on state power generation from other sources over the same and earlier time periods to see if, in fact, fossil fuel consumption is reduced by the presence of wind generation, and if so, by how much. Since wind generation is erratic, it would be useful to know which alternative sources (fossil fuel vs. nuclear vs. hydro) are dialed down when wind plants are producing. The strength of this analysis could be enhanced by similar information from the states of Vermont, Pennsylvania, and West Virginia, where there are also wind generation facilities in operation. Independent analysts have difficulty gaining access to these figures, perhaps because the data are not favorable to the wind industry.

2. General quality of the DEIS

² "The Effects of Integrating Wind Power on Transmission System Planning, Reliability, and Operations, Report on Phase 2: System Performance Evaluation," prepared for NYSERDA by GE Energy et al., March 4, 2005, p. 7.16. See also "The Effects of Integrating Wind Power on Transmission System Planning, Reliability, and Operations, Report on Phase 1: Preliminary Overall Reliability Assessment," prepared for NYSERDA by GE Energy et al., February 2, 2004. Both are posted on the NYSERDA website: www.nyserdera.com

³ *Ibid.*

The Noble Environmental DEIS is a document remarkably naïve of useful data. Data there is, or at least lists of information and tables of numbers which were measured in some way, but the measurements and numbers stop short of demonstrating anything meaningful, even when comparisons are made. Ecology and Environment, Inc. has created for Noble Environmental a soothing, pleasing, and mind-numbing document whose conclusions, section after section, are unsupported assertions of a most vague nature. Problems are masked by inadequate data gathering or presentation. There is no interest in realistic solutions even when problems are documented. The document relies heavily on the unspoken assumption that our presumption is that the project has no environmental impact. If this is the case, inadequate data leads us back to the conclusion that the project has no environmental impact, because the presumption, or null hypothesis as it is called in science, has not been disproven. In reality our presumption in requiring a study of environmental impact is that the impact is significant, and the burden of proof rests with Noble Environmental and its contractor, Ecology and Environment, to demonstrate that the project's environmental impact is sufficiently low relative to the social and economic benefits to be gained. If the data is inadequate or not pertinent to the problem at hand, then our presumption of significant environmental impact has not been disproven.

It is hardly surprising that the creators of this document lack commitment to a scientific approach or to environmental protection, however, given the website description of what Ecology and Environment offers its clients:

"The right environmental permitting strategy can mean the difference between spinning assets and a multi-million dollar write-off. E & E provides strategic environmental permitting approaches to get you the permits you need ahead of schedule and with the operational flexibility you need. From site selection and planning through construction, startup and long-term compliance, E & E's nationwide team specializes in environmental consulting services. We get the approvals you need to get your project on-line ahead of the competition." (<http://www.ene.com/services/power.asp>)

This approach is not the intent of SEQRA.

The graphic of a wind turbine presented in several locations in the DEIS (Figure 1-3, for example) is deceptive because it does not represent rotor size accurately relative to the height of the tower. Hub height is marked as 80 m, while rotor diameter, marked as 77 m, is represented graphically by a diameter only 59% of what it should be to be proportional to the hub height. Thus the rotor, whose blade reaches essentially half-way down the tower (77 m being approximately equal to 80 m), is represented graphically as a little pinwheel in this diagram. Little jagged lines are added on either side of the tower base to further the illusion that the tower is even taller compared to the rotor size. This diagram is reproduced in the Avian Risk Assessment to misrepresent the rotor-swept area, a critical concept with regard to avian impacts.

3. Safety from lightning, fires, falling turbines, dislocated pieces of turbine, or ice throw.

In section 2.29.1 and 2.29.3, the DEIS fails to acknowledge that none of the fire departments it names has the capability to fight fires in turbine nacelles (generator and gear box) 265 ft. above the ground. Turbine nacelles contain significant amounts of lubricants and hydraulic fluids. Fires may be started by lightning or brake malfunction. A fire may leave wind turbine controls malfunctioning until the equipment in the nacelle is repaired or replaced, making it more susceptible to accidents.

The Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances allow wind turbines to be erected 500 ft. from roads, 587 ft. (1½ times the total height) from buildings or above-ground utilities, and 1000 ft. from off-site homes. None of these distances are safe with regard to projectiles thrown from spinning 126 ft. turbine blades 390 ft. in the air, such as ice or pieces of blade, which can travel over 1600 ft. In Germany in 2003, in high storm winds, brakes on a wind turbine failed and the blades spun out of control. A blade struck the tower and the entire nacelle flew off the tower. The blades and other parts landed as far as 1650 ft (0.31 mile) from the base of the tower.⁴ This was an "upwind," three-bladed, industrial-sized turbines like those in the Project; "downwind" turbines have not been built since the 1980's. This distance is nearly identical to calculations of ice throw from turbines with 100 ft. blades rotating 20 times per minute (1680 ft) made by a Rutgers University physics professor.⁵

The "Health and Safety Plan" in section 2.29.2 and Appendix P is an exercise in vagueness and promise, without substance, as is "Fire Safety Planning" in 2.29.3. "Ice shed" in section 2.29.5 does not provide for adequate protection for cars driving past turbines 500 ft. away. "Generally," this paragraph reads, "ice buildup slows a turbine's rotation and will be sensed by the turbine's control system, causing the turbine to shut down" (DEIS p. 2-193). "Generally" is not good enough, nor is reliance on a mechanical system without the back-up of adequate setback. There are no plans or preventive measures for lightning strikes or other significant accidents. The most important preventive measure, adequate setback, has not been taken.

Both these considerations – the problems with fire-fighting and the possibilities for projectile throw – were raised with the Ellenburg Town Board before the Wind Energy Facilities Ordinance was passed. The board had the knowledge they needed to build safer setbacks into the ordinance but failed to do so.

Wind turbines themselves cause irregularities in the power supply as wind speed changes, including power surges as the wind gusts. Residents living near a new wind turbine installation in Meyersdale, PA, which came on line in December 2003, have had to replace stove elements and small appliances due to power surges which started at that time. Residents of Lincoln Township, WI, near a wind installation noticed an increase in lightning strikes in their area after the turbines went on-line in June 1999. Two computers protected by surge protectors and a TV set, all in different houses, were simultaneously "fried" one evening when lightning struck a nearby wind turbine tower.⁶

The DEIS does not discuss lightning precautions or data on lightning strikes from other installations. A search on the word "lightning" yields one hit, in Appendix P, with regard to performing a "risk analysis" and developing a safety plan sometime in the future. The time, however, is now, before permits are issued to allow construction.

4. Seismic activity

DEIS Section 2.1.3, in full:

"According to the USGS, which maintains records extending back to 1638 [sic], two significant earthquake epicenters (magnitude 5.0 or greater) have been recorded in the region. The Project Site is located within a low to moderately active seismic region. One magnitude 5.8 quake occurred in the Massena, New York area in 1944 and one quake with magnitude between 5.0 and 5.9 occurred South of Montreal, Quebec in 1877. Both areas are located between 50 and 100 miles from the Project Site.

⁴ See photos at http://www.pbase.com/wp/wind_turbine_photos.

⁵ Personal communication, Prof. Terry Matilsky, Dept. of Physics and Astronomy, Rutgers Univ., Piscataway, NJ.

⁶ Bittner-Mackin, F. 2003. "Excerpts from the final report of the Township of Lincoln Wind Turbine Moratorium Committee." 12-4-03.

However, no earthquake epicenters with a magnitude of 6.0 or greater have been recorded within 100 miles (U.S. Geological Survey 2006). In addition, no significant tectonic faults have been mapped in Clinton County, and there are no known active faults (i.e., younger than 1.6 million years) in this region (U.S. Geological Survey 2002)" (DEIS p. 2-2).

DEIS Section 2.2.3:

"As described in Section 2.1.3, the USGS states that one significant earthquake epicenter (magnitude 5.2) has been recorded within 50 miles of the Project Site and that the Project Site is not located within an active seismic region (U.S. Geological Survey 2001). No significant tectonic faults have been mapped in Clinton County, and there are no known active faults (i.e., younger than 1.6 million years) in this region (U.S. Geological Survey 2002)" (DEIS p. 2-7).

The DEIS preparers cannot even figure out what they themselves are saying in these two contradictory paragraphs and they did not do their homework.

An earthquake of magnitude 5.1 according to the USGS and 5.5 according to the Canadian Geological Survey with an epicenter 15 miles southwest of Plattsburgh occurred on April 20, 2002, at latitude 44.51 and longitude -73.66, 25 miles from the proposed project site. This earthquake was felt all over New York, New England (to Maine), and down to Maryland. Clinton and Essex Counties were declared federal disaster areas due to \$4.06 million worth of damage to roads, buildings, and wells.⁷

Dr. Frank Revetta, professor of earth science and geophysics at SUNY Potsdam and director of the Potsdam Seismic Network, states, "There is an east-west trending gravity high north of the Adirondacks in northern New York [which] correlates with a belt of earthquakes of shallow depth (<18 km). This is the most seismically active area in New York State."⁸

Small quakes of less than magnitude 4 are frequent in the region, including a 3.3 earthquake in Plattsburgh on 5/24/02, two 3.0 earthquakes with epicenters close to that of the larger 4/02 earthquake on 6/25/02 and 12/25/02, a 3.5 earthquake centered in Owl's Head on 4/8/03, and a 2.5 earthquake 3 miles west of the village of Malone on 3/3/05. An earthquake with magnitude 3.7 (4.1 according to the Canadian Geological Survey) occurred on January 9, 2006, just north of the Canadian border 5 miles from the village of Churubusco, NY, the location of Noble Environmental's Clinton project, and 12 miles from the Ellenburg project and 15 miles from Altona. "There is a belt of earthquakes that extends from the Adirondacks into Western Quebec," Professor Revetta said to the Plattsburgh Press-Republican. "You can expect earthquakes there quite frequently."⁹

It is unclear whether Noble Environmental's omission of this publicly available information was accidental and careless or deliberate and deceptive, but with regard to public safety neither type of oversight is acceptable. The proposed wind turbines are nearly 400 ft. tall. They are slender columns of tubular steel with a 60-ton nacelle and hub of the 40-ton propeller at 265 ft. The DEIS contains no data on the stability of industrial wind turbines in the presence of earthquakes despite a significant quake occurring 25 miles from the Ellenburg project site four years ago and frequent smaller quakes as close as

5 miles from project sites. A 500-587 ft. setback is not adequate to protect the public or leaseholders from harm should a structure of this weight, nearly 400 ft. tall, fall over. For reasons of public safety the setbacks specified in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances must be revised. Construction cannot be permitted under these conditions.

5. Noise and Noise-related Health Issues

The noise standards adopted in the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances are wind turbine "industry standards." As such they make things easier on the operators of wind turbines by allowing more noise, but they do not comply with community noise standards promulgated by non-industry agencies such as the NYS DEC¹⁰ or the World Health Organization.¹¹

Compliance with NYS DEC noise standards (increasing the noise level no more than 6 dB over ambient) is anticipated to be almost non-existent near the Project: "Sound pressure increases of more than 6 dBA over existing conditions will occur at most residences within the vicinity of the Project" (DEIS p. 2-129). Though this information is included, it is discussed only with regard to the fact that legally there does not need to be compliance with this standard because NYS DEC is not the lead agency. There is no plan to mitigate these noise effects. This represents a significant alteration in noise levels judged by state agency (DEC) standards and a significant change in community character, quietness being an important part the community character which leads people to build and live in rural areas.

In Lincoln Township, WI, a University of Wisconsin survey of residents near a 22 turbine installation in 2001, 2 years after construction, documented that 44% of residents 800 ft to ¼ mile from the turbines found noise to be a problem in their households, 52% ¼ to ½ mile away, 32% ½ to 1 mile away, and 4% 1 to 2 miles away. Under certain conditions the turbines could be heard up to 2 miles away.¹² These numbers correspond well to measurements made by Dr. GP van den Berg of the University of Groningen in the Netherlands near a more recent 30 MW, 17 turbine installation on the Dutch-German border, where residents living 500 m (1640 ft, or 0.31 mile) and more from the turbines were reacting strongly to the noise, and residents up to 1900 m (1.2 miles) away expressed annoyance.¹³

In a 2005 survey of 200 adult residents within ¾ mile of the French St. Crepin Windfarm, 83% responded. Of these, 27% considered the noise to be intolerable at night, 58% considered the noise to be disturbing, and 10% considered the noise to be disturbing by day. This is only a 6 turbine, 9 MW installation.¹⁴

Dr. van den Berg has now published his research as a book (his dissertation) which is available on-line at <http://dissertations.uu.rug.nl/faculties/science/2006/g.p.van.den.berg/>; introductory and concluding chapters are reproduced in the accompanying material. His work focuses on figuring out why noise from

wind turbines carries so much farther than expected and on developing new acoustic models based on known properties of the atmosphere to improve the current poor accuracy of acoustic modeling in predicting how loudly and how far noise will carry from wind turbines. The introductory chapter provides an engaging, readable description of both the scientific and political aspects of the debate about wind turbine noise. Van den Berg's research also points to design features which could be incorporated into newer turbines which would both improve their efficiency and reduce the annoying types of noise they make.¹⁵

The audible noise produced by wind turbines has a thumping, pulsing character, especially at night, when it is louder. The noise is louder at night because of the contrast between the still, cool air at ground level and the steady stream of wind at the level of the turbine hubs, known as a "stable atmosphere" in which there is little vertical movement of air.¹⁶ This nighttime noise travels long distances. It has been documented to be disturbing to residents 1.2 miles away from wind turbines in regular rolling terrain,¹⁷ and 1.5 miles away in Appalachian valleys.¹⁸ Van den Berg documents how mountainous terrain can either lessen or increase the effect of a stable atmosphere in allowing sound to travel further.

At night, the WHO recommends, the level of continuous noise at the outside a dwelling should be 45 dB or less, and inside, 30 dB or less. The wind turbine noise at levels permitted by the Ellenburg, Clinton, and Altona Wind Energy Facilities Ordinances are in the range of decibel levels which disturb sleep, even if permitted noise levels are not surpassed. Higher levels of noise disturb sleep and produce a host of effects on health, well-being, and productivity.¹⁹ These and other health effects of excessive community noise are documented in the WHO report with reference to scientific and medical literature. These include:

- For people to understand each other easily when talking, environmental noise levels should be 35 dB or less. For vulnerable groups (hearing impaired, elderly, children in the process of reading and language acquisition, foreign language speakers, and children with developmental disabilities) even lower background levels are needed. When noise interferes with speech comprehension, problems with concentration, fatigue, uncertainty, lack of self-confidence, irritation, misunderstandings, decreased work capacity, problems in human relations, and a number of stress reactions arise.²⁰
- Effects of noise-induced sleep disturbance include fatigue, depressed mood or well-being, decreased performance, and increased use of sedatives or sleeping pills. Measured physiologic effects of noise during sleep are increased blood pressure and heart rate, changes in breathing pattern, and cardiac arrhythmias.²¹ Certain types of nighttime noise are especially bothersome, including noise which has impulses rather than being continuous, noise combined with physical

²¹ *Ibid.*, p. 44.

vibration, noise with low-frequency components,²² and sources in environments with low ambient background noise.²³ Children, the elderly, and people with preexisting illnesses, especially depression, are especially vulnerable to sleep disturbance.

- Noise has an adverse effect on performance over and above its effects on speech comprehension. The most strongly affected cognitive areas are reading, attention, problem solving, and memory. Children in school are adversely affected by noise, and it is the uncontrollability of noise, rather than its intensity, which is most critical. The effort to tune out the noise comes at the price of increased levels of stress hormones and elevation of resting blood pressure. The adverse effects are larger in children with lower school achievement.²⁴
- What is commonly referred to as noise "annoyance" is in fact a range of negative emotions, documented in people exposed to community noise, including anger, disappointment, dissatisfaction, withdrawal, helplessness, depression, anxiety, distraction, agitation, and exhaustion.²⁵ The percentage of highly annoyed people in a population starts to increase at 42 dB, and the percentage of moderately annoyed at 37 dB.²⁶

Participants in noise studies are selected from the general population and are usually adults. Vulnerable groups of people are underrepresented in studies, and if included, would show stronger effects at lower levels of noise. Vulnerable groups include the elderly, people who are sick or have chronic medical conditions, people with depression or other forms of mental illness, babies and young children in general, children with developmental disabilities, children dealing with complex cognitive tasks such as reading acquisition, and people who are blind or hearing impaired. These people may be less able to cope with the impacts of noise exposure and at greater risk for harmful effects than is documented in studies. Attention needs to be paid to them when developing noise setbacks requirements.

There are additional symptoms reported by neighbors of industrial wind turbine installations. Amanda Harry, MD, a British physician, found near a 16-turbine installation in 2003 that 13 out of 14 people surveyed reported an increase in headaches, and 10 reported sleep problems and anxiety. Other symptoms included migraine, nausea, dizziness, palpitations, stress, and depression.²⁷ Dr. Harry's study is in preparation for publication.

Many individual accounts from across the world support the same set of symptoms (in submitted material and clinical interviews I have performed as part of a study in progress). Based on accounts and interviews, and in discussion with Dr. Harry, I have defined the Wind Turbine Syndrome, a complex of symptoms which start when local turbines go into operation and resolve when the turbines are off or when the person is out of the area. The symptoms include:

- Sleep problems: audible noise or physical sensations of pulsation or pressure make it hard to go to sleep and cause frequent awakening.

²⁷ Milner, C. 2004. "Wind farms make people sick who live up to a mile away." *Sunday Telegraph*, 1-23-04; and personal communication from Dr. Harry.

- Headaches which are increased in frequency or severity.
- Dizziness, unsteadiness, and nausea.
- Exhaustion, anxiety, anger, irritability, and depression.
- Problems with concentration and learning.
- Tinnitus (ringing in the ears).

Not everyone near turbines has these symptoms. This does not mean people are making them up; it means there are differences among people in susceptibility. These differences are known as risk factors. Defining risk factors and the proportion of people who get symptoms is the role of epidemiologic studies, which are in progress.

Chronic sleep disturbance is the most common symptom. Exhaustion, mood problems, and problems with concentration and learning are natural outcomes of poor sleep.

Sensitivity to low frequency noise is a potential risk factor. Some people sense low-frequency noise as pressure in the ears rather than heard as sound, or experience a feeling or vibration in the chest or throat.²⁸ Neighbors of industrial wind turbines describe the distressing sensation of having to breathe in sync with a rhythmic pulsation from the turbines which is not necessarily audible, especially at night when trying to sleep.²⁹

Preexisting migraine disorder is emerging as a risk factor for sensitivity to Wind Turbine Syndrome. Migraine is not just a bad headache, but rather a complex neurologic phenomenon that affects the visual, hearing, and balance systems and at times motor control and consciousness itself. Many people with migraine have increased sensitivity to noise and to motion – they get carsick as youngsters, seasick, or very sick on carnival rides. Migraine-associated vertigo (which is the spinning type of dizziness, often with nausea) is a described medical entity. Migraine occurs in 12% of Americans. It is a common, familial, inherited condition.

To keep our balance and feel steady in space, we use three types of input: from our eyes, from stretch receptors in joints and muscles, and from balance organs in the inner ear. At least two of these systems have to be working, and agreeing, to maintain balance. If the systems don't agree, as in seasickness or vertigo, one feels both ill and unsteady. Wind turbines impinge on this system via the visual disturbance

Kabes & Crystal Smith, "Comments on Noise," and "Comments on Health," and "Comments on Shadow Flicker," and "Comments on Sleeplessness," Lincoln Township Wind Turbine Survey, University of Wisconsin Extension/Cooperative Extension, May 15, 2001; Linda Cooper, "Activist shares wind power concerns," *Pendleton Times (Franklin, W Va.)*, March 3, 2005, p. 4; Misty Edgecomb, "'Whoosh' spells uneasy progress: Many say wind . . . turbines are noise, nuisance," *Democrat & Chronicle (NY)*, December 4, 2005; Pam Foringer, "Our Fenner wind farm story," *Malone Telegram*, Autumn 2004; "Neighbors complain of wind farm nuisances," *Albuquerque Tribune*, April 28, 2006; Seth Robson, "Noisy turbine annoys neighbours," *Stuff.CO.NZ*, August 11, 2003; Nick Churchouse, "Manawatu residents say they are being 'driven stupid' by the sound," *Dominion Post (NZ)*, November 16, 2005; "Flurry of complaints after wind change," *TVNZ.CO NZ*, July 24, 2005; David Brierley, Letter to the editor, *Plattsburgh Press Republican*, November 1, 2004; Tom Vesesky, "Waymart facility troubles residents," *ZWIRE.COM (PA)*, May 16, 2005; Gwen Burkhardt, "Wind farm illness," *Western Mail (UK)*, June 6, 2005; Kathy Webb, "And the beat goes on . . . and on and on," *Hawke's Bay Today (NZ)*, February 18, 2006; "Wind turbine meeting," *Newsquest Media Group Newspapers (UK)*, July 27, 2005; Eleanor Tillinghast, "The dark side of wind power," *Malone Telegram*, February 12, 2005; Donald E. Goetz, "Promises gone with wind," *Seranton Times Tribune (PA)*, February 7, 2004.

of the moving blades and shadows, and, I hypothesize, by low-frequency air pressure waves impinging on the balance organs of the inner ear.

Older people are may also be at increased risk for effects because of age-related problems with the function of the inner ear or the nerves and parts of the brain which receive signals from the inner ear. Many healthy people age 57 to 91 have such problems: 5% have chronic dizziness, and 24% (tinnitus (ringing in the ears)).¹⁰ Older people often sleep less soundly and are more likely to have their sleep disturbed by noise.

Dizziness (specifically vertigo) and anxiety are neurologically linked phenomena,¹¹ so the anxiety and depression seen in association with other symptoms near wind installations are not necessarily an emotional response to symptoms, but may be a neurologically linked response to the balance disturbances themselves. Sleep deprivation also causes anxiety and depression.

Industrial wind turbines produce low-frequency as well as audible noise. Dr. Oguz Soysal, Professor and Chairman of the Dept. of Physics and Engineering at Frostburg State University in Maryland, measured sound levels over half a mile away from the 20 turbine wind farm in Meyersdale, PA, in 2005. Audible (A-weighted) dB (decibel) levels were in the 50-60 range, and audible plus low-frequency (C-weighted) dB were in the 65-70 range.¹² A difference of 10 dB between A and C weighting represents a significant amount of low-frequency noise by World Health Organization standards.¹³ Dr. van den Berg measured wind turbine sound spectra 750 m (0.47 mile) from a 17 turbine installation in 2002. His graphs reveal dB levels averaging 68-90 dB in the frequency range less than 10 Hz, and over 60 dB in the 10-100 Hz frequency range.¹⁴ Van den Berg states in his dissertation, "I agreed with delegate Jorgen Jakobsen, who presented a paper on low frequency wind turbine noise [Jakobsen 2004], that even though wind turbines did produce an appreciable amount of infrasound, the level was so far below the average human hearing threshold that it could not be a large scale problem"¹⁵ (emphasis added).

Dr. van den Berg shares the perception common in both the medical and acoustic fields that if you can't hear a noise, it can't affect you, but the world's leading researchers in the health effects of low-frequency noise exposure, Nuno Castelo Branco, MD (Head of the Scientific Board, Center for Human Performance, Alverca, Portugal, and Principal Investigator for the Vibroacoustic Disease Project supported by the Portuguese Ministry of Science and Technology) and Mariana Alvez-Pereira (a biomedical engineer at the New University of Lisbon) do not agree.

This international research group, centered in Portugal and including physicians from Poland, Russia, and the United States, has published extensively on the effects of low-frequency noise on parts of the body other than the ears, particularly on the cardiovascular, pulmonary, and neurologic systems.¹⁶ The

research, ongoing since the late 1980's, includes clinical, pathological, and experimental (animal model) investigations. The entity these physicians and PhD's describe, called Vibroacoustic Disease (VAD), includes fibrosis (laying down of additional fibrous thickening in the form of collagen) in the cardiovascular and pulmonary systems and seizures and cognitive changes in the brain. The disease is caused by long-term exposure to low-frequency noise (less than 500 Hz), most of which cannot be heard.

Just as we cannot detect X rays (because our eyes are not sensitive to this frequency) yet can be harmed by them, so we can be harmed by non-audible noise (pressure waves in the air), though our ears are not sensitive to them. The mechanism of this harm is the differing resonance frequencies of different parts of the human body, especially the chest and skull. Air pressure (sound) waves of certain wavelengths resonate inside these walled spaces, setting up vibrations to which the body responds by reinforcing its softer tissues with extra collagen, causing such problems as thickening of the pericardium (membrane inside which the heart beats) and cardiac valves, fibrosis of the lungs, and proliferation of glial (supporting) cells in the brain.

Vibroacoustic disease has been studied mostly in aviation workers (including pilots, flight attendants, and technicians) but is also found in other industries and community settings. One of the researchers, Mariana Alves-Pereira, a biomedical engineer, has recently compared the noise spectrum of an environment known to predispose occupants to VAD – the cockpit of a commercial jetliner – to the noise spectra of other common community settings. She finds that a variety of community settings have the low-frequency noise potential for causing VAD. She has examined noise measurements of industrial wind turbines provided to her by Amanda Harry, MD, and her collaborating acoustician, Dr. Manley in England and found the low frequency noise intensities to be in the range which can cause VAD, especially given prolonged in-home and overnight exposures. Alves-Pereira has also examined graphs of wind turbine sound pressure levels vs. frequency measured by van den Berg and considers the noise intensities at the lower frequencies to be concerning with regard to their potential for causing VAD. She is aware of the symptomatology of the d'Entremont family in Pubnico, Nova Scotia, who had to move out of their home 1000 ft. from a wind turbine, and notes the similarity of their symptoms to those of people with pathologically proven VAD. Part of our research in progress is to provide Alves-Pereira with additional wind turbine noise measurements.

Alves-Pereira has helped clarify how neighbors and town governments should be handling noise measurements related to wind turbines. An A-weighted decibel measurement misses all the low-frequency noise, since A weighting is designed to mimic the frequency response pattern of the human ear and screens out low-frequency noise. Rather than a single measurement of loudness, noise needs to be characterized by measurement of linear (unweighted) decibel levels in 1/3 octave bands across the sound frequency spectrum. Measurements should be taken inside homes, since the longer wavelengths in low-frequency noise resonate within rooms, magnifying their loudness relative to the outside. Low frequency noise also comes through walls with less attenuation than the 15 dB decrease assumed for audible noise.

Noble Environmental's analysis of noise impacts in this DEIS was technically inadequate with regard to current knowledge. Specifically:

- Ambient noise levels were not measured (Appendix H, Section 3.4, p. 3-3). Assumed rural background noise levels are too high, especially for nighttime, the critical time for noise.
- Sound intensity decreases with distance in complex ways depending on the frequency of the sound (low-frequency sound carries further and passes obstructions with less attenuation), the

"Balance disturbances in individuals with vibroacoustic disease." *Aviation, Space, and Environmental Medicine* 70, no. 3, section II:A96-99; Marciniak W, et al. 1999. "Electrocardiographic evaluation of 485 aeronautical workers exposed to different noise environments." *Aviation, Space, and Environmental Medicine* 70 (3 Pt 2):A46-53.

stability of the atmosphere (turbine noise carries further in a stable atmosphere as occurs at night), and the presence of reflective surfaces (increased propagation across open or frozen lakes or in the presence of a temperature inversion providing a reflective atmospheric layer). The discussion of sound propagation on p. 3-3 of Appendix H is oversimplified and allows for underestimation of the distances to which turbine noise is predicted to be propagated.

- Modeling of sound transmission did not look at the worst case scenario of the nighttime stable atmosphere, and thus underestimated the amount of noise likely to occur at various distances from the turbine installation at night, the critical time in terms of disturbance and health effects. Dr. Leventhall, the project acoustics consultant, is aware of these more accurate models of sound propagation from wind turbines but did not require them to be used in the modeling, showing negligence in his function as a technical consultant.
- The statement on p. 3-10, "Nor would use of alternative equipment further reduce sound levels," may apply to equipment which can be purchased right now but not to equipment which may be designed in the near future to vary blade pitch during rotation as recommended by van den Berg to reduce or eliminate the nighttime thumping which develops in stable atmosphere.³⁷ There is a rush to build because the developer stands to make a lot of money, while from the point of view of community sustainability of this type of development it would make sense to wait a few years until equipment which solves the nighttime noise problem is available.
- The measurement of wind turbine noise at Fenner Wind Farm to screen for low frequency noise occurred over a 17 minute period during the day, though van den Berg points out that to eliminate the interference of wind blowing on the microphone (which can confuse the issue of whether there is low frequency noise) it is better to measure at night under conditions of atmospheric stability (little to no wind at ground level, substantial wind at turbine hub height).
- The acoustic weighting network (or lack of a weighting network) used for the Fenner noise sample was not specified.
- Dr. Leventhall, the Project consultant, dismisses the low-frequency noise documented in this measurement [note rise in dB level on the left, low-frequency sides of the graphs] as irrelevant for two reasons: 1) Interference with microphone noise, and 2) below range of human hearing. Point (1) could be corrected by measuring at another time of day/atmospheric condition, and (2) is contradicted by the research on vibroacoustic disease. Dr. Leventhall does not go so far as to say that there is no low-frequency noise, just that it is "not unusual," in which he is accurate. Wind turbines in general produce low-frequency noise,³⁸ which is a problem elsewhere and is likely to be a problem here, too.

In summary, this Project has substantial potential for adverse noise effects on neighboring residents for which adequate studies have not been performed nor realistic mitigation proposed. Noise impact analysis was performed in a superficial fashion ignoring current knowledge so as to bias results in favor of the developers. Realistic mitigation with current technology means adequate setback. The Academy of Medicine of France has recommended a 1.5 km (0.96 mile) setback because of noise and health issues;³⁹ ours should be at least this. Delaying the Project until the technology is available for varying of blade pitch to increase efficiency and decrease noise would also be appropriate.

6. Shadow flicker

³⁷ van den Berg, GP. 2006. "Sound of high winds."

³⁸ Ibid., p. 4-5

³⁹ Chouard, Claude-Henri. 2006. <<Le retentissement du fonctionnement des éoliennes sur la santé de l'homme>> ("The repercussions of wind turbine functioning on human health"). Academie Nationale de Medecine (French National Academy of Medicine).

When turning with the sun behind them, turbine blades cast moving shadows across the landscape and houses, creating as a strobe effect within houses which can be difficult to block out. Some people lose their balance or become nauseated when they see the movement of shadows or the movement of the huge blades themselves. As with car or sea sickness, such symptoms occur when the three organs of position and movement perception (the inner ear, eyes, and stretch receptors in muscles and joints) do not agree with each other: the eyes perceive movement while the ears and stretch receptors do not. People with a personal or family history of migraine, or migraine-associated phenomena such as car sickness or vertigo, are more susceptible to these effects. The strobe effect also has the potential, like other flashing lights, to trigger seizures in people with epilepsy.

In Lincoln Township, WI, two years after installation of 22 industrial wind turbines, 33% of residents 800 ft to ¼ mile from the turbines found shadows from the blades to be a problem, 40% ¼ to ½ mile away, 18% ½ to 1 mile away, and 3% 1 to 2 miles away.⁴⁰

Seventy-one houses will be subjected to shadow flicker from the Ellenburg Project (DEIS p. 2-115). No mitigation measures were proposed, but rather indefinitely deferred: "Site-specific mitigation will be proposed for residences where turbine shadow impacts are predicted." (DEIS p. 2-117) The only realistic form of mitigation is setback, which is inadequate under Ellenburg municipal law. From the Lincoln Township data, setback of at least one mile is needed.

7. Birds and bats

The federal government is concerned enough about the potential wildlife mortality due to wide scale development of wind turbines that the GAO (Government Accountability Office) issued a lengthy report in September 2005⁴¹ and the National Academy of Sciences commissioned a 20-month study whose period does not end until December 2006:

"The National Academies will establish an expert committee of approximately 14 members to carry out a scientific study of the environmental impacts of wind-energy projects, focusing on the Mid-Atlantic Highlands as a case example. The study will consider adverse and beneficial effects, including impacts on landscapes, viewsheds, wildlife, habitats, water resources, air pollution, greenhouse gases, materials-acquisition costs, and other impacts. Using information from wind-power projects proposed or in place in the Mid-Atlantic Highlands and other regions as appropriate, the committee will develop an analytical framework for evaluating those effects that can inform siting decisions for wind energy projects. The study also will identify major areas of research and development needed to better understand the environmental impacts of wind-energy projects and reduce or mitigate negative environmental effects. The approximate starting date for the project is April 21, 2005. A pre-publication report will be issued at the end of the project in December, 2006."⁴²

I refer below to a letter to Patrick McCarthy at Ecology and Environment from David Stilwell, Field Supervisor, US Fish & Wildlife Service, dated May 13, 2005.⁴³ This letter is appended to the Environmental Assessment Form on the Noble Environmental website at:

<http://www.noblepower.com/our-projects/ellenburg/documents/NEPEburgSEQR-EAF.pdf>

Since Noble Environmental locked its website against copying or printing (despite their avowed commitment to "transparency"), the attached reproduction is reduced in size and blurred but still legible. The original may be viewed on the website.

Under *Recommendations* in the above letter (Stilwell to McCarthy, 5-13-05), the USFWS states, "Pre-construction studies of bats for this location are recommended. These studies should be of sufficient rigor to determine the temporal and spatial distribution of resident and migrating bat and bird species in and adjacent to the project area during various weather conditions (e.g. fog, rain, low cloud ceilings, clear skies, etc.)." Further, "In order to determine the potential collision-hazard for a particular site, and to account for annual variability, the spatial and temporal uses of the project airspace by birds and bats need to be defined during a multi-year period. This can best be accomplished by using remote sensing technology (radar, acoustic, and infrared) to collect data in various spatial and temporal scales (day and night, season to season, and year to year). Traditional sampling protocols (e.g. visual observation and/or mist netting) may be appropriate to supplement the remote sensing work and would likely be necessary to ground truth the data for individual species. Survey techniques are currently evolving and the project sponsor should work closely with this office and the New York State Department of Environmental Conservation (NYSDEC) to develop a draft study design prior to conducting any studies. Survey results should also be submitted to us for review and comment, along with proposed project-specific avoidance and minimization methods to reduce the risk of bat and bird mortality."

Multi-year studies were not done. Results have not been submitted to USFWS for review, or if they have, USFWS comments have not been included with the DEIS. Of note, too, is that David Stilwell, Field Supervisor, USFWS, who wrote the above-reference letter to Noble Environmental, strongly criticized the Avian Risk Assessment (ARA) created by the same environmental consultants, Ecology and Environment, Inc., of Lancaster, NY, for the Chautauqua Wind Project in Chautauqua, NY.⁴⁴ Many of the critiques leveled at the Chautauqua ARA apply to the ARA in the DEIS for Ellenburg, Clinton, and Altona. These include the need for multi-year studies of bird and bat migration (because of the variability in migration timing and location with wind and weather patterns, variability noted within years and year to year), the limitations of mobile radar in detecting small migrating birds and bats, and the role in observer effort in getting realistic information even about the presence of particular species, especially the more critical rare species. As for Chautauqua, there is no data in the ARA for Ellenburg, Clinton, and Altona which pertains to population densities or numbers, yet this is the critical information to have if we are going to be able to assess, in future, the effects of large-scale industrial wind power development on bird and bat populations.

I contacted Timothy Sullivan, the biologist at USFWS in Cortland, NY, (607-753-9334) responsible for the Noble projects in Clinton County, on May 30, 2006. He would like to review the ARA for Ellenburg, Clinton, and Altona as his supervisor. David Stilwell, indicated in his letter of May 13, 2005 would be appropriate, but has not had the time to do this given other responsibilities and the many wind projects under development in NYS. The intensity of development right now, in other words, is undermining our governmental oversight procedures. As I am, he is concerned that the cumulative effect of multiple industrial wind power installations in or just above the St. Lawrence River Valley will have a negative impact on migratory birds of a variety of types. Passerine or songbirds are in a general state of population

⁴³ David Stilwell, USFWS Field Supervisor, Letter to Patrick McCarthy dated 5-13-05.

⁴⁴ David Stilwell (signatory) and Timothy Sullivan (biologist), October 12, 2005, "Comments on our review of 2004 Avian Risk Assessment Report, Chautauqua Wind Project."

decline related to the cumulative effects of many insults, including habitat destruction, fragmentation, and loss of quality; impacts with buildings, cell towers, power lines, and other tall objects; and cats and cowbirds (predator accessibility related to habitat fragmentation).

With regard to birds, sensitive species in or near the project area include the Bald Eagle (threatened in NYS), Northern Harrier (a large open-country hawk, threatened in NYS), Pied-Billed Grebe (a small waterfowl, threatened in NYS), Sedge Wren (a wetland species, threatened in NYS), Bicknell's Thrush (a rare eastern thrush, imperiled in NYS), and Common Loon (vulnerable in NYS). Other birds common to our area and on the NYS "Species of special concern" list are Cooper's and Sharp-shinned hawks, Northern Goshawk, Osprey, and American Bittern.

The DEIS description of where Snow Geese occur is inaccurate. Snow Geese use farmlands at least as far west as Malone and east to Lake Champlain in a broad front which is expanding year by year. In fact, we are located in the only flyway (and stop-over, for replenishing energy reserves) of the Greater Snow Goose in the world.⁴⁵ Snow geese spend the month of November and most of December here; Canada Geese arrive earlier and disappear about the same time. Geese and other waterfowl use as part of their migratory pathway extensive wetlands along the St. Lawrence River in Quebec. Just over the border from Fort Covington (Franklin County) is the Réserve nationale de faune du lac Saint-François, "created mainly to protect exceptional wetland habitat on the shores of Lac Saint-François that is used by a variety of aquatic and land birds and shelters a number of rare animal and plant species" (website of the Canadian Wildlife Service).

Ground surveys for spring "migratory" birds were done on only May 25 and 26, 2005, though bird migration through our area runs from late March to late May or so; timing and intensity varies year to year. The birds detected were local breeders, but most of the species detected at this time locally are migrant species which winter elsewhere and fall under the Migratory Bird Act. The methodology used – fine-minute detection periods by seeing or hearing – is an adaptation of the Breeding Bird Survey technique which has no applicability in this situation, and serves only to limit, by extreme limitation of observer effort, the numbers of species detected. There is no attempt made to estimate population numbers or density in any way. The similar technique used for the Breeding Bird Surveys in early and late June, 2005, with 3-minute detection periods, is also inadequate to obtain data on population sizes. This technique was developed to have a uniform way to get simple, limited data from disparate untrained observers across the country. It is not a recognized way of estimating bird population densities or numbers (see references⁴⁶ for discussion).

Bat methodology was limited to visual nighttime monitoring in a beam of infrared light and use of bat call detector devices. Very small numbers of bats were detected in the beams. The preparers of the DEIS discuss how the visual and radar data were not similar, so dissimilar that they considered these two forms of measurement to be "independent," though of course they were not independent since they were measuring the same phenomenon (birds and bats flying overhead) at the same time; the unrelatedness of the data obtained reflects measurement problems, not "independence" of data sets. At any rate, the visual studies do not allow one to calculate the proportion of "targets" in the radar study which were bats and birds because the two sets of measurements were so different they did not seem to reflect the same nightly

phenomenon. The call detector devices were mounted on silos in farmland, and allowed identification of four species between the two sites. As for bird migrant studies, limitation of effort limited the numbers of species detected and no data was collected on population densities or numbers.

Discussion of bat impacts does not reflect findings of large bat kills by wind turbines on Appalachian ridges and the correlation of bat kill with a generating vs. non-generating spinning turbine blade.⁴³

Comparisons of numbers such as rates of radar target objects picked up at the different wind plant sites surveyed is meaningless without statistical analysis, since even superficial inspection of the data presented in the graphs in the radar monitoring study show wide variability day to day. When data is variable, it is more likely that average values pulled from such data sets do not differ from each other. This is a most basic concept in statistics which is ignored in the data presentation in the ARA. It is also unclear what point the preparers were trying to make in presenting such comparisons.

To provide references and discussion of adequate migratory bird monitoring, the USFWS comment on the Chautauqua Wind Project DEIS is attached. The sites are different but the methodologic inadequacies are the same, produced by the same contractor, Ecology and Environment.⁴⁴

In summary, there has not been adequate oversight of wind power development proposals by USFWS due to the agency being overwhelmed by the number of such proposals in the state, yet such oversight and coordination of bird and bat population issues across broad geographic fronts is badly needed, as recognized by the initiation of two federal level agency studies in the last year which focus on wildlife issues. The current Project needs to be delayed for such review to take place, and to bring the bird and bat studies closer to compliance with USFWS recommendations by having the developers sponsor at least another year of wildlife studies. USFWS oversight to bring the studies methodologically closer to usefulness, in terms of obtaining population data, is recommended.

8. Non-avian wildlife

With regard to terrestrial and aquatic wildlife, information in the DEIS is thin and suggests both incompetence and lack of effort. Habitat and foraging requirements of the White-tailed deer and Black bear are described with mention that suitable habitat occurs within the Project Area, but population estimates are notably lacking. Pre-construction deer and bear population counts by methods well known to wildlife biologists would be appropriate to allow post-construction comparisons. Without this data, the effects of wind turbine construction on game species cannot be assessed. To my knowledge before and after population comparisons have not been done for other wind turbine projects in New York State or adjacent states, though hunting is a major recreational activity in rural areas and resident accounts from other wind turbine sites report relative scarcity of deer after construction. This project is the second large windplant proposed for NY State, the first being the Tug Hill Project (120 turbines) built last summer. Many additional projects are in the planning stages. Given SEQRA's focus on cumulative effects, I

See reports by Merlin Tuttle, Greg Johnson, Edward B. Arnett, Wally Erickson, Jessica Kerns, Brian Cooper, and Jason Horn. See Edward B. Arnett (Bat Conservation International), Letter regarding wind company distortion of bat research, June 5, 2005.

⁴⁴ David Stilwell (signatory) and Timothy Sullivan (biologist). October 12, 2005. "Comments on our review of 2004 Avian Risk Assessment Report. Chautauqua Wind Project."

strongly recommend that before further projects go into construction, including this one, that wildlife biologists controlled by NYSDEC obtain two years' worth of population data on significant game species to allow valid post-construction comparisons, and that turbine complexes not be built across a wide area until post-construction data is available for a limited number of sites.

In the DEIS, further discussion of mammals and other vertebrates is relegated to Table 2.9-1, a list by habitat. This table misses even common species such as red squirrel, weasel species, mink, marten, fisher, otter, red fox, coyote, woodchuck, voles, mice, snowshoe hare, etc., which are common in our Adirondack foothills area, showing insufficient care and effort on the part of the preparers of the DEIS. Population data is again lacking. There is no mention of large predators with large home ranges which may include the project area, including cougar which are regularly seen from Altona into St. Lawrence County, including a video of a cougar with a cub filmed in northern Franklin County in 2003. The cougar is a federal endangered species officially considered to be extirpated in NY State, though it does occur and apparently breeds. Other large mammals of which there are reports in the area include bobcat, wolverine, wolf (also a federal endangered species considered extirpated in NY State), and moose. These species are not considered.

Existing research on the effects of wind turbines on wildlife is not mentioned. Lawrence Rabin, Presidential Management Fellow in the US Forest Service R&D in Washington, DC compared the behavior of two groups of California ground squirrels in similar environments, one close to wind turbines and the other not. To be published in a forthcoming issue of *Biological Conservation*, the study found that squirrels near turbines were more likely to dash back to their burrows when hearing an alarm call and spent more time looking around for predators. A possible reason for the squirrels' increased alertness is their need to compensate for their reduced ability to communicate through sound. Both behaviors can reduce reproductive success by reducing foraging time and increasing energy expenditure, and have the potential to be shared by a number of animal species.⁴⁹

The discussion of the potential impacts of the project on terrestrial wildlife is, like the discussion of wetlands, an account of inevitabilities and minimization without real content, including the failure to acknowledge the significance of potential impacts. Statements such as:

"Although the Project this [sic] will result in a local reduction in the amount of available forest habitat, this total acreage is minor in comparison with the overall acreage of forested land located in the Project Area." (DEIS p. 2-87)

ignore the issue of cumulative effect highlighted by SEQRA. The authors conclude soothingly, "Indirect impacts on wildlife will occur as a result of habitat alteration in association with construction and operation of the Project. However, these impacts are not expected to be significant" (DEIS p. 2-88), having presented no population data, no before-and-after wildlife population figures from other sites, nor even demonstrated basic competence in the wildlife field by presenting an accurate mammal list.

9. Wetlands

Ecology and Environment's disregard or perhaps ignorance of ecological principals is apparent throughout the DEIS, starting with the Executive Summary: "The loss of wetlands will be compensated for by the construction of new wetlands in the same watershed" (DEIS p. 2). An engineer or a backhoe operator can construct a wet place but not a wetland; wetlands have to regenerate and during regeneration will not support the same communities of plants, insects, invertebrates, fish, amphibians, birds, and

⁴⁹ "Wind turbines send wildlife diving for cover," *New Scientist*, Issue 2549, May 3, 2006, p. 18.

mammals as they did before they were disturbed. The type of wetland which regenerates depends on soil type, siltation properties, water flow, and the presence of beaver, and has a specific time course. These issues are given no consideration.

The sections of the DEIS on wetlands, particularly the Wetland Delineation Report in Appendix D, presents a variety of maps and detailed descriptions of methodology and the vegetation of different wetland areas within the project area, but does nothing significant with the information. The language used minimizes the importance, "functional value," and size of the various wetlands, and tells us soothingly that "Project facilities have been sited to minimize or avoid wetland impacts to the greatest extent practicable, while still being able to meet the Project objectives" (DEIS Appendix D, p. 7-2). We are being told that wetlands are not important. The possibility of siting changes during construction is left open and uncontrolled: "However, until the individual turbine sites are designed and the final grade contours are established, it is not possible to determine the actual extent of wetland impacts within the turbine sites" (DEIS Appendix D, p. 7-4). Mitigation plans are vague: "If avoidance of drainages and swales is not possible, the turbine site will be designed in such a way to allow for the continuation of the surface flow" (DEIS Appendix D, p. 7-5). Adjacent sentences contain conflicting, vague information: "No significant impacts are expected to streams in the Project Area as a result of construction or operation of the Ellenburg Windpark. Potential indirect impacts may result from construction activities, including increased sedimentation and turbidity caused by increased surface runoff from work areas" (DEIS Appendix D, p. 7-7).

The USACE has jurisdiction over all wetlands and waterways in the United States, regardless of size, which are connected hydrologically to a navigable waterway. This could be a marsh connected to a ditch to a stream to a river which eventually flows into the St. Lawrence River or other navigable waterway.

The USACE will not issue permits to place turbines in wetlands, because turbines don't need to be in wetlands and can be placed elsewhere. However, they issue permits (and require permits) for all crossing of waterways and wetlands in their jurisdiction by roads or power lines.

I spoke on May 31, 2006, with Kevin Bruce in the Albany Field Office of the US Army Corps of Engineers. 1 Bond St., Troy, NY 12180, 518-273-7420, fax 518-273-2055.

The USACE has received applications for all three Noble projects. Mr. Bruce said they are early in the process of reviewing the application for the Clinton project, and that review of the Ellenburg and Altona projects has not yet started. He is planning a site meeting in the 3rd week of June for the Clinton project.

Mr. Bruce told me he commonly is asked by project sponsors if they can go ahead and start constructing roads or break ground in areas of dry land not under the jurisdiction of the USACE before securing permits from the USACE. The USACE generally advises project sponsors not to do this, since the USACE might request changes in the project to avoid wetlands, including by access roads or power lines.

USACE review, which falls under the Clean Water Act and the National Environmental Policy Act, also triggers federal level review under the Fish and Wildlife Coordination Act and the National Historic Preservation Act.

In summary, it appears that extensive federal level review of the three Noble projects is still in the early stages. It would not be appropriate for the town boards, as the lead agencies, to issue building permits without certifying that the appropriate federal review processes have been completed and the required permits obtained, nor for Noble to proceed with construction without required federal permits.

It is not at all clear from the DEIS that state or federal law will be upheld in the Ellenburg Project with regard to wetlands. Because of the vagueness and apparent project dominance of decisions being made with regard to wetlands, on-site NYSDEC and federal (USACE) oversight will be critical to modify turbine placement decisions during the project planning phase, to oversee them (to prevent changes) during the construction phase, and to oversee other mitigation measures.

BY: *Theresa LaFoglia*

Dear Town Board Officials:

I would like to enter the following comments into the public record regarding the hearing held at the Ellenburg Town Hall on Wednesday, May 24, 2006 on Noble's Ellenburg Windpark application for a wind energy facility and the accompanying Draft Environmental Impact Statement (DEIS).

On a recent trip to the Tug Hill Windfarm (May, 2006), I observed only one occupied residence within the area of several of the 220' industrial wind turbines. On the other hand, several hundred people reside within the proposed windfarm areas planned for the Towns of Ellenburg and Clinton. These people will be severely negatively impacted by the erection of the proposed 440' wind towers in these townships.

I feel that the industrial wind turbines proposed to be located in the Towns of Ellenburg and Clinton will have a profoundly negative impact on the towns' environments and their citizens:

1) ... I can provide no statistical research supporting or refuting the amount of acceptable decibels of noise which will be produced by the wind turbines – However, I do know that those 220' turbines at the Tug Hill project emit a constant whistling sound and an additional whoosh as the blades pass the tower, a noise which can be equated to a harsh wind in a rainstorm; a loud wind that in this case remains constant.

2) ... I can recommend no acceptable set-back footage for the placement of the proposed wind turbines from area homes ~ However, I do know that the wind turbines at Tug Hill are scattered, appear random in placement (as they will be in Ellenburg and Clinton), and provide no visual consistency or grouping – many of the Tug Hill turbines are situated away family homes or farms - that will not be the case in Ellenburg and Clinton.

3) I can submit no concrete information pertaining to the vertigo produced by the varied speed of the wind turbines' rotating blades – those that are grouped closely together have blades turning at differing and dizzying rates of speed. The shadows produced – especially at dawn and dusk – will tortuously infiltrate nearby homes throughout the day.

4) Predictions of the numbers of birds and bats to be killed annually within these windfarm projects is reprehensible – no deaths of wildlife are acceptable – what right have we to predict numbers of deaths of birds and bats (in the hundreds annually!) and casually state that this is an acceptable limit! And is it also acceptable to knowingly alter the migratory paths of wildlife? No!

5) . . . Why is it acceptable to disrupt one acre of wetland and reconstruct two acres elsewhere. Sounds good, but what happens to the wildlife within the originally disrupted area? How do they know to relocate??

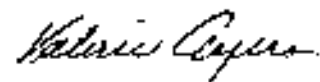

The above issues will certainly negatively impact our environment!

-2-

Finally, and most importantly, no statistical research, propaganda or monetary gifts, leases, or PILOT agreements will compensate for the loss of the beautiful, pristine, natural, countryside which I treasure. The erection of hundreds of 440' industrial wind turbines throughout our gorgeous agrarian countryside will negatively impact our viewshed and our environment in unspeakable ways – ways none of us can yet fully comprehend.

No statistical limits of bird and bat kills, noise decibels, vertigo, disruption of emergency cellular service, or tower setbacks are acceptable. My viewshed and environment will be significantly and negatively impacted by the construction of these industrial wind towers! These proposed projects are not only an affront to me but they will be especially detrimental and destructive to our beautiful natural landscape and environment!

Sincerely,

Valerie Ayers

June 4, 2006

Ellenburg Town Board
c/o 106 West Hill Road,
Ellenburg Center, NY.

In regards to Noble's DEIS report for Ellenburg, I feel impacts and unanswered solutions to these impacts would make this report incomplete and should make it unacceptable for the Town Board.

Approximately 2000 feet to the north of my house is a pond, including wetlands and marshes, which encompasses 20 or more acres that geese, ducks, blue herons etc have traveled to since I can remember back into the 1950's. The intensity of the proposed lined up wind turbines east and west, along the APA line and trailing off to the north and being less than a mile away has to impact the water fowl flight. In foggy weather, I cannot believe that they can avoid collision flying to and from this pond. If they should make it past the maze of wind turbines, they definitely will have to alter their flight path.

In the report non participant homeowners will be affected by excessive noise levels and shadow flicker. No solutions to this are made known to the public. Also incomplete reports of radio waves on people, wildlife and reception to TV, radio and cell phones and any solutions to any problems have not been noted.

What mentions are there of safeguards for unforeseen runoffs, oil spills from machines, and construction of cement footers (pads), and how it may affect the water table throughout the area?

For 68 and now 77 proposed Noble wind turbines, \$50,000 does not seem to be realistically acceptable if a crisis, such as a hurricane etc. should put out 8 or 10 wind turbines to the point of removal. If not taken down could further impact the environment.

I strongly urge the Town Board of Ellenburg to not accept Noble's DEIS report as complete until it is complete.

Respectfully,

Joseph M. Kramer

May 25, 2006

Thank you for the opportunity to comment. My name is Dereth Gilnea, Program Director with Citizens Campaign for the Environment (CCE). Supported by over 80,000 members, CCE is a non-partisan, non-profit advocacy organization working to protect the natural environment and public health. Our work is based on a philosophy of pollution prevention, conservation, and environmental sustainability.

CCE strongly supports increased investment and development of clean, renewable energy and in particular wind energy that has undergone a rigorous environmental review. CCE strongly believes that residents and local governments should make informed decisions on wind power projects based on their individual and specific merits and concerns, with the opportunity review proposals in an open and meaningful process.

As most of us already know, the consumption of energy generated by fossil fuels and nuclear power has serious impacts on human health, wildlife, plants, and the natural environment. The long list of detrimental consequences from our reliance on fossil fuel combustion and nuclear fission include, but are not limited to: acid rain, urban smog, higher rates of lung disease and heart failure, oil spills, contaminated drinking water, rising sea levels, mining impacts, global warming, ecosystem damage, nuclear waste disposal, national and global depletion of finite energy sources, and conflicts over the world's dwindling non-renewable sources. *In particular, increasing concentrations of mercury in fish and wildlife, as well as, the devastating effects of acid rain will continue to significantly impact the environment, economy, and character of the North Country.*

In general CCE strongly supports wind power projects that have undergone rigorous environmental review, for the following reasons:

- *Wind power is emission free.* In contrast to coal, oil, and gas plants, wind facilities do not burn fossil fuels and thus do not produce air pollution. Wind power does not require millions of gallons of water each day for cooling purposes, like fossil fuel and nuclear plants. Wind power is a commercially available, proven clean technology.
- *Wind power is independent of imported fuels.* Once constructed, a wind facility requires no fuel. This reduces our dependence on imported oil and gas, much of

which comes from unstable areas of the world. In times of rising and volatile fuel prices, domestic power production can hedge price fluctuations, increasing energy diversity and security.

- ***Wind power keeps energy dollars at home.*** Buying coal, oil, and gas sends New York dollars out of state and out of the country. In contrast, wind power keeps more of those dollars in-state. Investment in wind power can boost New York's growing renewable technologies industries. Wind facilities will also pay local property taxes or make payments in lieu of taxes.
- ***Wind power helps stabilize energy prices.*** By further diversifying the ways we produce electricity, wind power can help stabilize energy prices. Even a small drop in the demand for natural gas, for example, will bring down the price. This results in more price stability and lower overall energy costs.
- ***Wind power can help farmers and other landowners.*** In New York, many wind facilities will be sited on working farms, with farmers or other landowners paid through long-term leases. For farmers, this can be a new source of income that allows them to farm under and around the turbine. This adds to their property value and can help preserve working farms in New York.
- ***Wind power proposals must be carefully reviewed and sited.*** Renewable energy facilities, like any other form of electric generation, must go through a meaningful environmental review process and be carefully sited. Proposed wind facilities are subject to New York's State Environmental Quality Review Act (SEQRA), under which government decision-makers study a wide range of potential economic, environmental, and aesthetic impacts, develop any necessary mitigation measures and provide opportunities for public input. Furthermore, the potential impacts of wind turbines, as currently designed, on public health and wildlife species should be compared to the public health, pollution and ecosystem impacts of traditional fossil fuel generation. In this way, the impacts can be put into a meaningful perspective.

Specific comments on the Noble Ellenburg Windpark

Many individuals may be unfamiliar with modern wind turbines. New York State currently generates electricity from wind power from wind farms in the Towns of Madison, Fenner, and Weathersfield. Maple Ridge, in St. Lawrence County is the largest wind farm in the east.

According to the Draft Environmental Impact Statement (DEIS), the Noble Ellenburg Windpark is a 54 turbine (81MW) wind energy generating facility or windpark proposed for the town of Ellenburg, in Clinton County New York. The project will construct 11 miles of access roads, an electrical collection system, and a new substation to ensure the energy generated is safely and efficiently delivered to the grid. The project will effect less than 100 acres, it will disturb 7.2 acres of wetlands and permanently impact 1.7 acres. Noble has pledged to replace lost wetlands by a ratio of 2:1. Impacts to wildlife, including birds and bats will not be biologically significant. Based on mortality rates at other wind facilities in the U.S., the DEIS estimates that 125 individual different bird

species birds and zero (0) to 232 individual different species of bats could be killed per year. The project is expected to have no to minimal impacts to groundwater.

CCE believes that the Ellenburg Windpark positively benefits the environment, local rural economy, and public health. Over the 20 years, the Ellenburg Windpark is expected to reduce precursors to acid rain, Nitrogen Oxide (NOx) and Sulfur Dioxide, 3,674 and 7,682 tons, respectively. Additionally over 2.2 million tons of Carbon Dioxide (CO2), the chief green house gas contributing to global climate change (global warming) will be displaced as a result of this clean energy project.

In closing, CCE appreciates the opportunity to discuss our perspective with the residents of Ellenburg. Wind power offers innumerable environmental and economic benefits to the local community, the region, our state, and the nation as a whole. Deciding to host a wind farm in your community is a big decision. It is one that must be made considering all the facts and inclusive of all points of view. There are issues, such as aesthetics, that we must agree to disagree on. Many find these sleek turbines to be examples of "kinetic art," that hold the promise of a better future for our children. And just like other examples of art, there are those that disagree. These perspectives, while both valid, should not be the sole determining factor of whether your community decides to host a wind farm.

Thank you for the opportunity to comment.

Sincerely,

Dereth Glance

RE: Comments on the Proposed Noble Ellenburg Windpark

Citizens Campaign for the Environment (CCE), supported by over 80,000 members, is a non-partisan, non-profit advocacy organization working to protect the natural environment and public health. Our work is based on a philosophy of pollution prevention, conservation, and environmental sustainability.

CCE strongly supports increased investment and development of clean, renewable energy and in particular wind energy that has undergone a rigorous environmental review. CCE strongly believes that residents and local governments should make informed decisions on wind power projects based on their individual and specific merits and concerns, with the opportunity review proposals in an open and meaningful process.

As most of us already know, the consumption of energy generated by fossil fuels and nuclear power has serious impacts on human health, wildlife, plants, and the natural environment. The long list of detrimental consequences from our reliance on fossil fuel combustion and nuclear fission include, but are not limited to: acid rain, urban smog, higher rates of lung disease and heart failure, oil spills, contaminated drinking water, rising sea levels, mining impacts, global warming, ecosystem damage, nuclear waste disposal, national and global depletion of finite energy sources, and conflicts over the world's dwindling non-renewable sources. *In particular, increasing concentrations of mercury in fish and wildlife, as well as, the devastating effects of acid rain will continue to significantly impact the environment, economy, and character of the North Country.*

In general CCE strongly supports wind power projects that have undergone rigorous environmental review, for the following reasons:

- *Wind power is emission free.* In contrast to coal, oil, and gas plants, wind facilities do not burn fossil fuels and thus do not produce air pollution. Wind power does not require millions of gallons of water each day for cooling purposes, like fossil fuel and nuclear plants. Wind power is a commercially available, proven clean technology.

- *Wind power is independent of imported fuels.* Once constructed, a wind facility requires no fuel. This reduces our dependence on imported oil and gas, much of which comes from unstable areas of the world. In times of rising and volatile fuel prices, domestic power production can hedge price fluctuations, increasing energy diversity and security.
- *Wind power keeps energy dollars at home.* Buying coal, oil, and gas sends New York dollars out of state and out of the country. In contrast, wind power keeps more of those dollars in-state. Investment in wind power can boost New York's growing renewable technologies industries. Wind facilities will also pay local property taxes or make payments in lieu of taxes.
- *Wind power helps stabilize energy prices.* By further diversifying the ways we produce electricity, wind power can help stabilize energy prices. Even a small drop in the demand for natural gas, for example, will bring down the price. This results in more price stability and lower overall energy costs.
- *Wind power can help farmers and other landowners.* In New York, many wind facilities will be sited on working farms, with farmers or other landowners paid through long-term leases. For farmers, this can be a new source of income that allows them to farm under and around the turbine. This adds to their property value and can help preserve working farms in New York.
- *Wind power proposals must be carefully reviewed and sited.* Renewable energy facilities, like any other form of electric generation, must go through a meaningful environmental review process and be carefully sited. Proposed wind facilities are subject to New York's State Environmental Quality Review Act (SEQRA), under which government decision-makers study a wide range of potential economic, environmental, and aesthetic impacts, develop any necessary mitigation measures and provide opportunities for public input. Furthermore, the potential impacts of wind turbines, as currently designed, on public health and wildlife species should be compared to the public health, pollution and ecosystem impacts of traditional fossil fuel generation. In this way, the impacts can be put into a meaningful perspective.

Specific comments on the Noble Ellenburg Windpark

Many individuals may be unfamiliar with modern wind turbines. New York State currently generates electricity from wind power from wind farms in the Towns of Madison, Ferris, and Weathersfield. Maple Ridge, in St. Lawrence County is the largest wind farm in the east.

According to the Draft Environmental Impact Statement (DEIS), the Noble Ellenburg Windpark is a 54 turbine (81MW) wind energy generating facility or windpark proposed for the town of Ellenburg, in Clinton County New York. The project will construct 11 miles of access roads, an electrical collection system, and a new substation to ensure the energy generated is safely and efficiently delivered to the grid. The project will effect less than 100 acres, it will disturb 7.2 acres of wetlands and permanently impact 1.7 acres. Noble has pledged to replace lost wetlands by a ratio of 2:1. Impacts to wildlife, including birds and bats will not be biologically significant. Based on mortality rates at

other wind facilities in the U.S., the DEIS estimates that 125 individual different bird species birds and zero (0) to 232 individual different species of bats could be killed per year. The project is expected to have no to minimal impacts to groundwater.

CCE believes that the Ellenburg Windpark positively benefits the environment, local rural economy, and public health. Over the 20 years, the Ellenburg Windpark is expected to reduce precursors to acid rain, Nitrogen Oxide (NOx) and Sulfur Dioxide, 3,674 and 7,682 tons, respectively. Additionally over 2.2 million tons of Carbon Dioxide (CO2), the chief green house gas contributing to global climate change (global warming) will be displaced as a result of this clean energy project.

In closing, CCE appreciates the opportunity to discuss our perspective with the residents of Ellenburg. Wind power offers innumerable environmental and economic benefits to the local community, the region, our state, and the nation as a whole. Deciding to host a wind farm in your community is a big decision. It is one that must be made considering all the facts and inclusive of all points of view. There are issues, such as aesthetics, that we must agree to disagree on. Many find these sleek turbines to be examples of "kinetic art," that hold the promise of a better future for our children. And just like other examples of art, there are those that disagree. These perspectives, while both valid, should not be the sole determining factor of whether your community decides to host a wind farm.

Thank you for the opportunity to comment.

To the Town Board of Ellenburg.

Why are we restricted to the 440 ft. wind turbines? Wouldn't more local people be employed on the wind turbine projects if the wind turbine companies went with the 90-ft. wind turbines instead? Why would the town not consider the employment of more local people a good thing? Wouldn't the maintenance of a smaller wind turbine be in the favor of local people? Isn't there cranes in the general area that could service a 90-ft. wind turbine? I'm sure there must be local people who could use an opportunity for work closer to their homes.

I can't understand why everyone I ask including the wind turbine companies wouldn't answer these questions. Wasn't the whole reason for having these companies come to Ellenburg was to boost the local economy? It seems to me that a smaller wind turbine being worked on by local people would be better for the focal economy than a 440 ft. wind turbine done almost entirely by outside laborers.

Anne Sylvester

 May 30, 2006

Ellenburg Town Board
 106 West Hill Road
 Ellenburg Center, New York 12934

Dear Town Board Officials:

I would like to enter the following comments into the public record regarding the hearing held at the Ellenburg Town Hall on Wednesday, May 24, 2006 on Noble's Ellenburg Windpark application for a wind energy facility and the accompanying Draft Environmental Impact Statement (DEIS).

On a recent trip to the Tug Hill Windfarm (May, 2006), I observed only one occupied residence within the area of several of the 220' industrial wind turbines. On the other hand, several hundred people reside within the proposed windfarm areas planned for the Towns of Ellenburg and Clinton. These people will be severely negatively impacted by the erection of the proposed 440' wind towers in these townships.

I feel that the industrial wind turbines proposed to be located in the Towns of Ellenburg and Clinton will have a profoundly negative impact on the towns' environments and their citizens:

1) ... I can provide no statistical research supporting or refuting the amount of acceptable decibels of noise which will be produced by the wind turbines – However, I do know that those 220' turbines at the Tug Hill project emit a constant whistling sound and an additional whoosh as the blades pass the tower, a noise which can be equated to a harsh wind in a rainstorm; a loud wind that in this case remains constant.

2) ... I can recommend no acceptable set-back footage for the placement of the proposed wind turbines from area homes – However, I do know that the wind turbines at Tug Hill are scattered, appear random in placement (as they will be in Ellenburg and Clinton), and provide no visual consistency or grouping - many of the Tug Hill turbines are situated away family homes or farms - that will not be the case in Ellenburg and Clinton.

3) ... I can submit no concrete information pertaining to the vertigo produced by the varied speed of the wind turbines' rotating blades – those that are grouped closely together have blades turning at differing and dizzying rates of speed. The shadows produced – especially at dawn and dusk – will tortuously infiltrate nearby homes throughout the day.

4) ... Predictions of the numbers of birds and bats to be killed annually within these windfarm projects is reprehensible – no deaths of wildlife are acceptable – what right have we to predict numbers of deaths of birds and bats (in the hundreds annually!) and casually state that this is an acceptable limit! And is it also acceptable to knowingly alter the migratory paths of wildlife? No!

5) ... Why is it acceptable to disrupt one acre of wetland and reconstruct two acres elsewhere. Sounds good, but what happens to the wildlife within the originally disrupted area? How do they know to relocate??

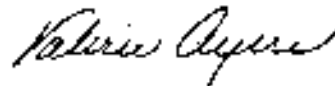

The above issues will certainly negatively impact our environment!

-2-

Finally, and most importantly, no statistical research, propaganda or monetary gifts, leases, or PILOT agreements will compensate for the loss of the beautiful, pristine, natural, countryside which I treasure. The erection of hundreds of 440' industrial wind turbines throughout our gorgeous agrarian countryside will negatively impact our viewshed and our environment in unspeakable ways – ways none of us can yet fully comprehend.

No statistical limits of bird and bat kills, noise decibels, vertigo, disruption of emergency cellular service, or tower setbacks are acceptable. My viewshed and environment will be significantly and negatively impacted by the construction of these industrial wind towers! These proposed projects are not only an affront to me but they will be especially detrimental and destructive to our beautiful natural landscape and environment!

Sincerely,

Valerie Ayers

Received Time May, 17, 12:22PM

May 17, 2006

This is being presented by a group of concerned citizens who live in the Town of Ellenburg. We feel that it is time to negotiate setbacks, noise levels and other pertinent issues. An example of what could be acceptable is enclosed.

Thank you for your careful consideration in this matter.

The following is a draft of a Wind Energy Conversion System (WECS) ordinance prepared by North Country Advocates, with legal assistance, in the Spring of 2005

Proposed Local Law No ___ of the Year 2005

Section 1. Being enacted by the Town Board of the Town of Malone, a new chapter 78 of the Code of the Town of Malone as follows:

Chapter 78

WIND ENERGY CONVERSION FACILITIES

§ 78-1. Findings and purpose.

- A. New public policies directed at "green energy" production, accompanied by Federal and State government subsidies intended to achieve specified goals, have resulted in new interest in harnessing wind power to generate electricity. In September 2004 the NYS Public Service Commission announced a green energy goal of 25 percent of the total electricity generation in the State of New York by 2013.
- B. As the result of such policies, so-called "wind farms" are being proposed in areas of the state where wind power is deemed sufficient for large-scale facilities. Additionally, it is anticipated, individual wind turbines may be proposed for individual residences, farms and other uses.
- C. Experience in this country and in others has indicated that wind farms have the potential for adverse impacts on wildlife (e.g., when placed in the path of bats and migratory birds). They may also adversely affect the quality of life of nearby residents through noise and shadow flicker from blades, and decrease property values as a result of this and degraded viewshed. Extensive road construction and maintenance, along with construction of related power lines and pylons and substations for connections into the power grid may also have adverse environmental impacts. Additionally, there are safety issues related to the height of wind turbines (falling over, blade throw, ice throw, and fire in the nacelle) and high voltage lines of direct concern to residents and to the Town which is obligated to provide fire protection.
- D. The intent of this chapter is to provide for the possible establishment of wind farms and individual wind turbines within the Town of Malone in appropriate locations, while protecting neighborhoods and minimizing the adverse visual and operational effects of these facilities. This chapter is intended to be implemented in conjunction with other provisions of the Town Code (particularly Zoning) and the State Environmental Quality Review Act (Environmental Conservation Law).
- E. The Town of Malone has undertaken a deliberative process to establish policy, standards and procedures related to the siting of wind farms, as contained herein and in chapter 79 (Zoning) and chapter 4 (Airport Approach Hazard Protection). In doing so, the Town has attempted to:
 1. Preserve property values and development opportunities;

2. Promote and protect the safety and general welfare of the municipality and its citizens;
3. Place fiscal responsibility for adverse effects on the owners of these facilities, and
4. Minimize the adverse environmental effects of these facilities.

§ 78-2. Definitions.

As used in this chapter, the following terms shall have the meanings indicated:

CLEAR AREA – Area surrounding a wind turbine to be kept free of habitable structures.

DISTRIBUTED GENERATION – Energy generation that is located at or near the end-user.

EAF – Environmental Assessment Form used in the implementation of the State Environmental Quality Review Act as that term is defined in Part 617 of Title 6 of the New York Codes, Rules and Regulations.

EIS – Environmental Impact Statement employed in the implementation of the State Environmental Quality Review Act as that term is defined in Part 617 of Title 6 of the New York Codes, Rules and Regulations.

HEIGHT – The height of a turbine measured to the tip of the blade at its highest point.

NACELLE – The frame and housing at the top of the tower that encloses the gearbox and generator and protects them from the weather.

PERSON – An individual, partnership, corporation, association, trustee, municipality or other legal entity, but shall not include the state or any state agency.

ROTOR – The blades and hub of the wind turbine that rotate during the turbine operation.

STATE ENVIRONMENTAL QUALITY REVIEW ACT (SEQRA) – Article 8 of the Environmental Conservation Law, which is Chapter 43-B of the Consolidated Laws of the State of New York.

UNDERTAKE – The commencement of a material disturbance of land, including commencement of road construction, grading, installation of utility, clearing, excavation or other material disturbance of land preparatory or incidental to a wind energy conversion facility or wind monitoring tower.

WIND ENERGY CONVERSION FACILITY – All equipment, machinery, and structures utilized in connection with the conversion of wind to electricity. This includes, but is not limited to, all transmission, storage, collection and supply equipment, turbines, substations, transformers, wind monitoring or meteorological towers, site access, service roads and

machinery associated with the use. A wind energy conversion facility may consist of one or more wind turbines.

WIND FARM – A wind energy conversion facility with two or more wind turbines.

WIND MONITORING OR METEOROLOGICAL ("TEST" or "MET") TOWER Tower used for supporting anemometer, wind vane and other equipment to assess the wind resource at a predetermined height above the ground.

WIND TURBINE - A device that converts kinetic energy of the wind into rotational energy to turn an electrical generator shaft. A wind turbine typically consists of a rotor, nacelle and supporting tower.

s 78-3. Special use permit required.

- A. No wind energy conversion facility or wind monitoring tower shall be erected, moved, changed or altered, other than replacement in kind in the same location, except after approval and issuance of a special use permit in conformance with the provisions of this chapter and no person shall undertake such a land use prior to the issuance of said permit.
- B. Each wind energy conversion facility and wind monitoring tower shall be deemed an allowable special use within any zoning district where it is listed as such. Where these uses are not listed as allowable, the uses are prohibited.
- C. The Town Board shall review and make final determinations on all applications for wind energy conversion facilities and wind monitoring towers.
- D. The Town Board may seek the recommendation of the Planning Board during its review of any application.

s 78-4. Pre-application procedures.

- A. Prior to the filing of an application for a special use permit under this chapter, the applicant is encouraged to meet with the Town Board at a public meeting to discuss the proposed wind energy conversion facility in general terms.
- B. The Town Board will meet with the applicant within 21 days following a written request submitted to the Town Clerk. If the Town Board fails to meet with the applicant within 21 days of such request (unless an extension of time is granted), the applicant may proceed with a special use permit application.
- C. The purpose of the pre-application conference, to be held as a public proceeding, is to inform the Town Board and citizens of the town as to the general nature of the proposed wind energy conversion facility. The applicant is encouraged to prepare sufficient preliminary architectural and/or engineering drawings to inform the Town Board and interested citizens of the location of the facility and its scale and overall design. The board may use the opportunity to clarify the filing requirements.

- D. Within 30 days of the pre-application conference, or within 21 days of filing an application for a special use permit, the applicant shall arrange for a balloon or crane test to illustrate the height of the proposed facility. The date, time and location of such test shall be advertised in the official newspaper at least 14 days, but not more than 21 days prior to the test. In addition, individual notices shall be provided to the Town Board and all adjoining landowners.

§ 78-5. Application requirements: wind energy conversion facility.

- A. An application for a special use permit for a wind energy conversion facility shall include the following general information:
- (1) Name, address, telephone number and original signature of the applicant and all co-applicants. Co-applicants may include the landowner of the project site or the operator of the facility. If telecommunications antennae are proposed, a telecommunications carrier must be a co-applicant.
 - (2) Documentation of the applicant's legal right to install and use the proposed facility on the subject property at the time of application. Documentation should also include proof of control over the setback or clear areas, if required under s. ____ Control shall mean legal authority to prevent the use of any structure within the setback or clear area for human habitation or other use permitting human occupancy, e.g., an executed easement or binding contract.
 - (3) If the applicant will be represented by an agent, the name, address and telephone number of the agent as well as an original signature of the applicant authorizing the agent to represent the applicant.
- B. An application shall also include the following information (in duplicate or the number of copies specified by the Town Board) relating to the location of the proposed facility:
- (1) Postal address and tax map page, block and lot or parcel number of the subject property.
 - (2) Zoning district(s) in which the subject property is located (with an annotated copy of the Town zoning map).
 - (3) A line map to scale showing the lot lines of the subject property and all properties within 500 feet of the property lines, as well as the location of all buildings (identified as to use) including accessory structures, on all the properties shown.
- C. An application shall include the following information and documents relating to siting and design of the facility:
- (1) A one-inch-equals-40 feet vicinity map of the subject property and adjacent properties within 300 feet of the property lines, signed and sealed by a licensed professional engineer depicting the following:

- a. **Property lines for the subject property and all adjacent properties within 300 feet.**
- b. **Watercourses, natural features and contours at each two feet.**
- c. **Existing vegetation including tree cover and average height of trees on the subject property and adjacent properties.**
- d. **Outline of all existing buildings, including use or purpose (e.g., residential buildings, garages, accessory structures, etc.) on subject property and all adjacent properties within 300 feet with distances, at grade, from the proposed wind energy conversion facility to each building on the vicinity plan.**
- e. **Location of all existing roads on the subject property and on all adjacent properties within 300 feet.**
- f. **Proposed location of the proposed wind energy conversion facility, including all turbines, fencing, associated ground equipment, transmission infrastructure and power lines (specifying above-ground or below-ground), cable locations, parking areas, access roads and any other construction or development attendant to the wind energy conversion facility.**
- g. **Representation of location of viewpoint for the sight-line diagram referenced below.**

(2) **Sight lines and photographs as described below:**

- a. **Sight-line representation drawn from representative locations that show the lowest point of the turbine tower visible from each location. Each sight line shall be depicted in profile, drawn at one inch equals 40 feet. The profiles shall show all intervening trees and buildings. There shall be at least two sight line representations illustrating the visibility of the facility from surrounding areas such as the closest habitable structures or nearby public roads or areas.**
- b. **Color photographs of the proposed site from at least two locations accurately depicting the existing conditions.**
- c. **Annotated photographs: existing condition photographs with the proposed wind energy conversion facility superimposed on it to accurately simulate the facility when building and illustrate its total height, width and breadth.**

(3) **Siting elevations or views-at-grade from the north, south, east and west for a 50 foot radius around the proposed wind energy conversion facility. Elevations shall be**

shown at either one-quarter inch equal one foot or one-eighth inch equal one foot scale which show the following:

- a. Wind energy conversion facility and, if applicable, the security barrier and associated equipment, with total elevation dimension of all parts of the facility.
- b. Security barrier: if the barrier will block views of the wind energy conversion facility, the barrier drawing shall be cut away to show the view behind the barrier.
- c. Any and all structures on the subject property.
- d. Existing trees and shrubs at current heights and proposed trees and shrubs at proposed height at time of installation, with approximate elevations dimensioned.

(4) Equipment and materials to be used in/on the facility including the following:

- a. Specifications for all equipment associated with the proposed facility.
- b. Materials specified by type and specific treatment.
- c. Colors of the facility represented by a color board showing actual colors proposed.

(5) A landscape plan depicting existing trees and shrubs and describing the specimens proposed to be added or removed, identified by species and size of specimen at installation and their locations.

(6) A lighting plan depicting the following:

- a. All required FAA lighting, identified as such. The application shall include a copy of the determination by the Federal Aviation Administration to establish required markings and/or lights for the structure.
- b. If other lighting is proposed, a manufacturer's computer-generated point-to-point printout, including the horizontal foot-candle levels at grade, within the subject property to be developed and 25 feet beyond the property lines. The printout shall indicate the locations and types of luminaires proposed.

D. An application shall include a report identifying existing noise levels and the maximum future project noise levels from the proposed wind energy conversion facility (which, according to this ordinance, must not exceed 30 dB (C) at the property line or beyond). Such report shall be certified and signed by a State of New York certified acoustic engineer, stating that noise projections are accurate.

- E. An application shall include information relating to the construction/installation of the wind energy conversion facility as follows:
 - (1) A construction schedule describing commencement and completion dates; and
 - (2) A description of the routes to be used by construction and delivery vehicles, the gross weights and heights of those loaded vehicles.
- F. An application shall provide a demonstration of financial resources sufficient to undertake, complete and operate the wind energy conversion facility, obtain adequate insurance to protect adjacent properties, and provide a surety to guarantee removal and disposal of the facility when it is abandoned or inoperative (see s 78-10, E, below: Decommissioning bond).
- G. An application shall include a completed Environmental Assessment Form, Part I, in fulfillment of State Environmental Quality Review Act (SEQRA) requirements.
- H. At the time of filing, the applicant shall pay an application fee in the amount of fifty (\$50) per megawatt of wind turbine nameplate capacity and a sum (which may be deposited into an escrow fund) sufficient to cover the cost to the Town of obtaining legal and technical assistance to review the application and review and/or prepare environmental impact studies.

s 78-6. Standards applicable to wind energy conversion facilities: location

- A. Wind farms may be located only within the following zoning districts:
 - Countryside District
 - Open Space District
- B. Individual wind turbines may be located in the following zoning districts, provided the Town Board finds all other applicable standards are met:
- C. In addition to the zoning district limitations, no wind energy conversion facility shall be located within 1,000 feet of the following areas of county-wide and regional significance:
 - 1. Adirondack Trail (measurement from the road center line).
 - 2. Military Trail (measurement made from road center line or official designation boundary).
 - 3. Seaway Trail (measurement made from road center line).
 - 3. Salmon River (measurement made from shoreline as determined on WSGS 7 1/2 quadrangle topographic maps).

- D. In addition to the other restrictions on locations, all wind energy conversion facilities and wind monitoring towers and wind turbines must conform to current Federal Aviation Administration (FAA) regulations regarding "objects affecting navigable airspace" (see Code of Federal Regulations, Title 14: Aeronautics & Space, Part 77—Objects Affecting Navigable Airspace, Subpart C—Obstruction Standards, para 77.21 [Scope] and para. 77.23 [Standards for determining obstructions]). According to these FAA regulations, there can be (a) no structure higher than 200 feet (total height) above the established airport elevation within 3 nautical miles, (b) no structure higher than 300 feet (total height) above the established airport elevation within 4 nautical miles, (c) no structure higher than 400 feet (total height) above the established airport elevation within 5 nautical miles, and (d) no structure higher than 500 feet (total height) above the established airport elevation within 6 nautical miles. Note that 1 nautical mile = 1.15 miles. Thus, a 300 foot high (total height) structure could not be erected within 4.6 miles of the Malone-Dufort Airport, and a 400 foot high (total height) structure could not be erected within 5.75 miles of the Malone-Dufort Airport.

s 78-7. Standards applicable to wind energy conversion facilities: design

- A. The site and proposed mitigation shall eliminate or minimize any impact on the visual character of surrounding neighborhoods and the community.
- B. Wind energy conversion facilities shall be painted a non-reflective color that blends with sky and clouds.
- C. All equipment necessary for monitoring and operation of a wind energy conversion facility shall be contained within the turbine tower. If this is infeasible, ancillary equipment may be located outside the tower, provided that it is contained within an underground vault, or enclosed within a separate structure or behind a year-round landscape or vegetated buffer.
- D. Wind turbines shall be lighted only if required by the Federal Aviation Administration (FAA). Lighting of equipment and other structures shall be shielded from adjoining properties.
- E. Signs on the facility shall be limited to (i) those needed to identify the property and the owner and to warn of danger; and (ii) educational signs providing information on the technology and renewable energy usage.

s 78-8. Standards for wind energy conversion facilities: environmental

- A. Wind energy conversion facilities shall be designed to minimize land clearing and fragmentation of open space areas and shall avoid permanently protected open space when feasible. Wind turbines shall be sited to make use of previously developed areas wherever possible. Such facilities shall also be located in a manner that does not have significant negative impacts on rare animal species in the vicinity, particularly bird and bat species. The Town of Malone will hire a biologist(s), whose services will be paid for by the applicant, for a two-year (2-year) study of bird and bat populations and migration at the proposed wind farm

site(s). This will include on-the-ground population assessments and mobile radar assessments of night-time migration in spring and fall, both for two (2) full annual cycles (as is recommended by the National Audubon Society).

- B. Wind energy conversion facilities shall be located in a manner consistent with all applicable state and Federal wetlands laws and regulations.
- C. Storm-water run-off and erosion control shall be managed in a manner consistent with all applicable state and Federal laws and regulations.
- D. The maximum height of any wind turbine shall be 350 feet [Editor: This height limit needs further discussion before it is set in stone. Possibly a shorter height is desirable, more along the lines of 200 feet total height].
- E. Wind turbines shall be set back a minimum of one and one-half (1.5) miles from the closest residence or agricultural barn, provided that the owner of the project site may choose to waive this setback requirement.
- F. Wind energy conversion facilities shall be sited in a manner that does not result in shadowing or flickering or strobing impacts on nearby residences from rotating propellers (see 1.5 mile set-back).
- G. Wind energy conversion facilities, including turbines, shall be operated so that the noise emitted during all phases of operation (including wind turbine braking, re-starting, and turning of the propeller to face the wind) does not exceed 30 dB (C), as measured at the boundary of the project site or at any point farther away from the boundary of the project site. The Town of Malone shall hire a certified noise engineer, to be paid for by the applicant or current windfarm owner, to take noise measurements on a monthly basis, to verify that the windfarm is in compliance with this noise regulation of 30 dB (C).
- H. No hazardous materials or waste shall be discharged on the site of any wind energy conversion facility. If any such materials or wastes are to be used on the site, there shall be provided for full containment of such materials or waste. An enclosed containment area, designed to contain at least 110 percent of the volume of the materials or waste stored or used on the site may be required to meet this requirement. The facility shall also be designed to prevent unauthorized access, e.g., by a fenced enclosed or locked access.
- I. The maximum number of wind turbines within the jurisdiction of the Town of Malone is set at twenty (20), provided that individual wind turbines in excess of that number may be allowed to furnish electricity to a single property, which single property would be the property on which the turbine is erected.
- J. Approval shall be granted and a special use permit issued only if the Town Board finds that the facility meets all requirements of the State Environmental Quality Review Act.

~~s 78-9. Use of wind turbines by telecommunications carriers.~~

- A. Wind turbines may be used to locate telecommunications antennas, subject to applicable regulations governing such uses in Chapter 73 of this Code and subject to the requirements herein.
- B. All ground-mounted telecommunications equipment shall be located in either a shelter, within the wind turbine tower or otherwise screened from view year-round, either through effective landscaping or existing natural vegetated buffers.
- C. Antennas shall be flush-mounted to be in keeping with the design of the wind turbine tower and cabling associated with a personal wireless facility shall be contained within the tower structure or enclosed within a conduit painted to match the turbine mount.

§ 78-10. Review process and decision: wind energy conversion facilities.

A. Action on receipt of application.

- (1) Upon receipt of an application for a wind energy conversion facility, the Code Officer shall provide a recommendation to the Town Board regarding completeness under this chapter and environmental significance pursuant to the State Environmental Quality Review Act and regulations.
- (2) At its next regularly scheduled meeting, or a special meeting, the Town Board shall determine if the application is complete. If it is not, the applicant shall be informed of the information necessary for a complete application.
- (3) If the application is determined to contain all information required by this chapter, the Town Board shall make a determination of environmental significance pursuant to the requirements of SEQRA and otherwise implement that law and regulations.

B. Public hearing notices.

- (1) Upon determining that the application is complete pursuant to this chapter and SEQRA, the Town Board shall hold a public hearing within 62 days of the determination.
- (2) At least 10 days before the hearing, the Town Board shall mail a notice to the applicant and to the Franklin County planning board or agency as required by sec. 249-m of the General Municipal Law.
- (3) Public notice of said hearing shall be published in the official newspapers at least five days prior to the date thereof.

C. Public hearing.

- (1) The public hearing shall be conducted in compliance with the provisions of the New York State Open Meetings Law..
- (2) The Town Board may authorize a special moderator who is not a member of the board to conduct the hearing, provided that members of the board shall be present at the hearing.

D. Decision.

- (1) Within 62 days of the close of the public hearing, the Town Board shall issue its determination on the application, provided that this deadline for a final determination shall be extended in accordance with SEQR requirements.
- (2) The Town Board shall apply all the review standards set out in this chapter and shall apply SEQR in its consideration of the application and its final decision thereon.
- (3) The Town Board may impose such reasonable conditions and restrictions as are directly related to and incidental to the proposed wind energy conversion facility. Upon its decision of approval subject to conditions (precedent), the applicant must meet the specified conditions before a special use permit will be issued allowing the wind energy conversion facility to be undertaken.
- (4) The decision of the Town Board shall be in writing and reasons for approval, conditions of approval or disapproval shall be clearly and fully stated.
- (5) The decision of the Town Board shall be filed within five days in the office of the Town Clerk and a copy mailed to the applicant by certified mail, with return receipt requested.

E. Decommissioning bond.

Upon approval of such an application by the Town Board and prior to the issuance of a special use permit, the applicant shall provide a form of surety to assure that the wind energy conversion facility will be physically removed in its entirety upon abandonment or discontinuance of use as described in sec. 78- . To meet this surety requirement, the applicant shall provide a performance bond issued by a bonding or surety company, deposit funds in or a certificate of deposit issued by a bank or trust company located and authorized to do business in the state, provide an irrevocable letter of credit from a bank located and authorized to do business in the state, or provide such other surety as is consistent with subdivision nine of section two hundred seventy-seven of Town Law and is acceptable to the Town Board.

(An alternative to this clause would be the following: Applicant will give evidence of its ability to provide a cash bond to be held in an escrow account by the Town of Malone, for the decommissioning of the applicant's wind turbines and the remainder of the applicant's wind farm apparatus and installations, when the turbines have ceased operation or have been abandoned by the applicant or the applicant's legal successor(s). This bond will be used, as well, to pay compensation (a) to neighbors of the wind farm, (b) to the Town of Malone, and (c) to the individual(s) leasing his land to the applicant or its legal successors, should the applicant or its legal successors fail in the performance of any of the stipulations in this ordinance. The amount of this cash bond will be calculated by an independent engineer or other expert selected by the Town of Malone and paid for by the applicant, which independent expert will calculate the reasonable cost to the Town of removing all wind turbines and disposing of them, removing all other installations erected by the applicant or its legal successors, and restoring the land to its former condition. The restoration process will include the removal of the concrete base (footers) for each turbine and any other installation

erected by applicant or its legal successor. Applicant understands that before any construction whatsoever begins on its windfarm site, __ amount of this cash bond must be placed in an escrow account held by the Town of Malone with a payment schedule set by the Town for regular, monthly payments into this account. Prior to the beginning of any construction at the windfarm site, the applicant must post a minimum of __ of the total cash bond, as calculated by the above independent expert.

- F. If the approved facility is not substantially commenced within one year of issuance of the permit, the permit shall expire.

§ 78-11. Application, review procedures and standards: wind monitoring towers

- A. An applicant for a special use permit limited to a wind monitoring tower is encouraged to attend a pre-application conference with the Town Board as described in sec. 78-4.
- B. The application for a wind monitoring tower shall include such information as is specified in sec. 78-5, pars A and B ; subsection (4) of par. C; and such other information as the Town Board shall require.
- C. A wind monitoring tower shall be erected for a maximum of two years.
- D. The Town Board may require payment of a fee for expenses related to the delivery of any tower and surety to ensure its timely and safe removal.

§ 78-12. State Environmental Quality Review Act requirements.

- A. A wind farm is deemed to be a Type 1 action pursuant to the State Environmental Quality Review Act.
- B. An application for a wind farm shall include a full EAF. When an application is filed for a single wind turbine or wind monitoring tower, a short-form EAF may be accepted by the Town Board, provided that the board may require a full EAF. An applicant may choose to file an Environmental Impact Statement instead of an EAF.
- C. A fee shall be charged to the applicant for the review or preparation of a draft EIS, and scoping shall be considered part of the draft EIS for purposes of determining the fee. Such fees shall be the maximum allowable under Section 617.17 of Part 617 of the New York Codes, Rules and Regulations.

§ 78-13. Compatibility with other applicable state and Federal laws.

All wind energy conversion facilities and monitoring towers must comply with all other statutes and regulations of the state and Federal governments. No building permit shall be issued until all such approvals and permits have been issued.

§ 78-14. Monitoring, maintenance, modifications.

- A. After a wind energy conversion facility is completed, the applicant/permittee shall provide the Town Board with a certification from a licensed engineer that the facility has been constructed in accordance with all approved plans and all Federal, state and local requirements.
- B. Once a wind energy conversion facility is operational, the applicant/permittee shall submit to the Town Board, at annual intervals from the date of issuance of the special use permit, a report detailing operating data for the facility (including, but not limited to, days of operation, energy production, etc.)
- C. The Town Board may employ an independent licensed engineer, with costs to be reimbursed by the applicant/permittee (or paid from an escrow account for that purpose), to inspect the facility on a semi-annual basis to confirm continuing compliance with applicable regulations and the special use permit. The applicant/permittee shall allow this agent of the Town to enter for the purpose of such inspections, upon reasonable notice.
- D. The Town Board may employ an independent licensed engineer, with costs to be reimbursed by the applicant/permittee (or paid from an escrow account for that purpose), to take monthly measurements of noise emissions to confirm continuing compliance with this standard.
- E. The applicant/permittee shall maintain the wind energy conversion facility in good condition. Such maintenance shall include, but not be limited to, painting, structural integrity of the foundation and support structure, and security barrier, as well as maintenance of the buffer areas and landscaping.
- F. Notice shall be provided to the Town Board of any change in ownership of the facility.
- G. All modifications to a wind energy conversion facility after issuance of the special use permit shall require approval by the Town Board in accordance with this chapter.

§ 78-15. Abandonment or discontinuance of use.

- A. At such time that a wind energy conversion facility or wind monitoring tower is scheduled to be abandoned or operations discontinued, the applicant/permittee shall notify the Town Board by certified U.S. mail of the proposed date of abandonment or discontinuation of operations. In the event the applicant/permittee fails to give such notice, the facility shall be considered abandoned or discontinued if it is inoperative for 180 days.
- B. Upon abandonment or discontinuation of use, the applicant/permittee shall physically remove the wind energy conversion facility within 90 days of the date of abandonment or discontinuance. This period may be extended at the request of the applicant/permittee and the discretionary consent of the Town Board. "Physically remove" shall include, but not be limited to:
 - i. Removal of the wind turbine and tower, all machinery, equipment, equipment structures, security barriers and all appurtenant structures from the subject property;

- ii. **Proper disposal of all solid and hazardous materials and wastes from the site in accordance with Federal, state and local laws and regulations;**
 - iii. **Restoration of the site of the facility to its natural conditions, except that any landscaping, grading or below-grade foundation may remain [Editor: This is a contentious issue, as to whether the wind energy company must remove its concrete base/footer, measuring 30x30x10 or 30x30x30, when decommissioning its turbines. This will have to be discussed further].**
- C. **If an applicant/permittee fails to remove a wind energy conversion facility in accordance with this chapter, the Town shall have authority to enter the subject property and physically remove the facility in addition to any other penalties and remedies available in law and equity. In the event the Town exercises its authority to remove any or all equipment from the wind energy conversion facility, the applicant/permittee will bear the full cost of this action, which cost will be paid out of the applicant/permittee's (or their legal successor's) decommissioning bond (see s 78-10, E, above).**

[An alternative clause to this would be: The applicant agrees to pay the full cash bond, referred to above, within five (5) years of starting construction of its wind energy conversion facility. The applicant understands that this cash bond will be held in an escrow account by the Town of Malone, to be used by the Town to dismantle and dispose of the wind energy conversion facility (as well as all other structures, both above and below ground, installed by the applicant or his/her legal successors), as well as dispose of all above-ground power lines and pylons for connecting to the regional power grid, when the Town has determined that the wind energy conversion facility is no longer generating electricity beyond __ MW and is thus deemed by the Town to have been abandoned or no longer effectively used for power generation by the applicant or its legal successors. This cash bond may also be used by the Town to pay for any compensation to neighbors or the Town of Malone or the lessor of property to the applicant or its legal successors, should the applicant or its legal successors fail in the performance of any of the stipulations in this ordinance.]

s 78-16. Penalties and remedies for violations.

- A. **Any person owning, controlling or managing any building, structure or land who shall undertake a wind energy conversion facility or wind monitoring tower in violation of this chapter or in noncompliance with the terms and conditions of any permit issued pursuant to this chapter, or any order of the enforcement officer, and any person who shall assist in so doing, shall be guilty of an offense and subject to a fine of not more than \$350 or to imprisonment for a period of not more than six months, or subject to both such fine and imprisonment. Every such person shall be deemed guilty of a separate offense for each week such violation shall continue. The Town may institute a civil proceeding to collect civil penalties in the amount of \$350 for each violation and each week said violation continues shall be deemed a separate violation.**
- B. **In case of any violation or threatened violation of any of the provisions of this local law, including the terms and conditions imposed by any permit issued pursuant to this local law, in addition to other remedies and penalties herein provided, the Town may institute any appropriate action or proceeding to prevent such unlawful erection, structural alteration,**

reconstruction, moving and/or use, and to restrain, correct or abate such violation, to prevent the illegal act.

(It might be prudent to insert the following clause, perhaps as a substitute for some of the language in (A) or (B), immediately above: Should the applicant or its legal successors fail in the performance of any of the stipulations in this ordinance, the Town of Malone will notify the applicant or its legal successors of this failure and the applicant or its legal successors will be obliged to correct this failure-in-performance within 30 days of notification in writing by the Town. The Town will then re-inspect the wind energy conversion facility, hiring an expert of the Town's choosing and paid for by the applicant or its successors, to warrant that the failure in-performance has been corrected. The Town shall, at its discretion, oblige the applicant or its legal successors to shut down its wind energy conversion facility (including wind turbines) until this failure in-performance has been corrected. Should the applicant or its legal successors fail to correct any failure-in-performance within the above 30 day period, the Town may, at its discretion, notify the applicant or its legal successors that the wind energy conversion facility must be shut down within 90 days (of a letter of intent sent by the Town to the applicant or its legal successors). At the end of that 90 days, the Town may, at its discretion, begin using the above cash bond to dismantle the wind energy conversion facility.)

§ 78-17. Taxation.

The Town of Malone hereby stipulates that the owner(s) of a wind energy conversion facility shall be subject to property tax on the wind energy conversion facility, including but not limited to the wind turbines and other electricity generating equipment and other capital improvements on the windfarm. This section hereby disallows the State of New York exemption of local or property taxation of wind generating equipment (including wind turbines).

§ 78-18. Judicial review.

Any person aggrieved by any final order under this chapter may seek to have such order reviewed in the manner provided by Article 78 of the New York State Civil Practice Law and Rules.

 Section 2. Chapter 79 Zoning of the Code of the Town of Malone is amended to add the following provisions:

§ 79-10.3 Wind energy conversion facilities and wind monitoring towers.

A wind energy conversion facility or wind monitoring tower as defined in chapter 78 of this Code shall be allowable only in the C Countryside District and O-S Open Space District and only as a special use upon review, approval and a permit issued by the Town Board in accordance with chapter 78.

Addenda

June 2005

1. Preliminary engineering plans must include plans for constructing above-ground and buried power lines, and pylons, as these are needed to connect the windfarm to the regional power grid. The applicant must provide the Town with an environmental impact study for the construction of these power lines and pylons which, it is understood, will extend out beyond (perhaps many miles beyond) the applicant's windfarm. This environmental impact study will be conducted by a professional(s) hired by the Town and paid for by the applicant.

2. Applicant must submit its plans for underground power cables to a NY State Licensed electrician selected by the Town and paid for by applicant, for said electrician to verify that there will be no stray voltage emitted by any underground power lines and cables over the life-time of the wind turbines. Moreover, the applicant and its legal successor(s) is forbidden to discharge electricity from its wind energy conversion facility into the ground. A violation of this stipulation will result in (a) a [stiff fine] for the first offense, (b) closure of the wind energy conversion facility for [a period of x months] for the second offense, and (c) permanent closure of the wind energy conversion facility for the third offense. The applicant and its legal successor(s) agree to pay all legal costs of the Town in pursuing these penalties in a court of law or equity.

3. Applicant must submit its installation plans to a NY State licensed hydrologist or geologist selected by the Town and paid for by applicant, who will determine whether there is likely to be damage or other adverse effects on surrounding water wells, water table, or other underground water ecology. Applicant will be held financially liable for any contamination to or other adverse effect on any surrounding water wells.

4. Applicant must furnish a description of the routes used by construction and delivery vehicles and any road improvements that will be necessary in the Town to accommodate construction vehicles, equipment or other deliveries. Applicant will pay for all road improvements, alterations, or construction. Applicant or its legal successor(s) will be held financially liable for all erosion damage, road damage, and road drainage problems caused by its

activities over the life-time of the turbines.

5. Applicant and its legal successor(s) must agree in writing to maintain the wind turbines and all other equipment within the wind energy conversion facility in good running order, as specified by the manufacturer of the wind turbines and the manufacturer(s) of all other equipment within the wind energy conversion facility, so as not to cause noise harm to neighbors or to disturb wildlife or to create a fire or other safety hazard to the wind turbines or surrounding area. Should the wind turbines or other operating equipment within the wind energy conversion facility be left inoperative for __ period of time, the said wind turbines or other equipment within the wind energy conversion facility will be considered by the Town to be derelict or abandoned and will be dismantled by the Town, using the monies from the applicant's cash bond.

6. Applicant will provide the Town with a full and complete disclosure of its financial records, including income tax records, over the past decade, which will turn these over to a NY State Chartered Public Account hired by the Town and paid for by the applicant. This disclosure must reveal the applicant's full assets.

7. The Town will hire an engineer, paid for by the applicant or its legal successor(s), to perform semi-annual (twice a year) inspection reports to the Code Enforcement Officer, confirming compliance with all stipulations in this code and with industry practices.

United State Fish and Wildlife Service Reviews Avian Risk Assessment

The United States Fish and Wildlife Service (USFWS) sent two letters October 12, 2005 to David Perry, Executive Vice President of Chautauqua Windpower LLC, severely critical of the draft Avian Risk Assessment (ARA) completed by Chautauqua Windpower and its consultants for the proposed wind power development in the Towns of Ripley and Westfield, Chautauqua County, New York. The shorter of the two letters focuses on the ARA's attention to migrating and resident American Bald Eagles; the longer of the two letters consists of a broader evaluation of the ARA and its attention to all resident and migrating birds.

The following is a brief summary of the USFWS letters criticizing the risk assessment. The full text of the USFWS letters is available by clicking

Summary of the USFWS Critique

Both USFWS letters portray the ARA as consisting largely of bad science, full of internal contradictions, and coming to unfounded conclusions, which could not be supported by the ARA's unreliable base-line data. Both letters provide detailed explanations of why the ARA's base-line data drawn from incomplete, partial-year investigations undertaken during only one calendar year comprise inadequate preconstruction studies. The USFWS letters also clearly document with much detail why multi-year studies are necessary specifically for this project. Finally, the critiques detail why the USFWS cannot accept even the ARA's base-line data, let alone its analysis, predictive ability, or conclusions. The USFWS letters also state that the ARA inappropriately includes inaccurate information regarding interpretation and implementation of federal wildlife laws.

Letter regarding the ARA's treatment of resident and migrating American Bald Eagles

The letter regarding the ARA's study of resident and migrating bald eagles clarifies the USFWS views on the potential for the project to kill or injure migrating or resident bald eagles in the area. In their letter the USFWS disagrees strenuously with the ARA's finding that the project will not adversely affect bald eagles. The USFWS clearly states that existing information, both in the ARA and from other sources, indicates that the project poses a risk of injury or mortality to both migrating and resident bald eagles.

Contrary to the ARA's assertions, the USFWS letter documents the fact that bald eagles do use and can be expected to continue to use the project area both as residents and migrants. Despite the ARA's arguments, bald eagles will use the area for foraging, to test their territorial boundaries and as fledglings. The USFWS letter also states that more bald eagles will be expected to occur in the vicinity of the project than the ARA reports. The USFWS letter finds that the ARA's conclusions were based on conflicting, very limited, and unreliable data and that the information in the ARA does not support its conclusions.

The USFWS letter criticizes statements made in the ARA that are unsupported by fact. As an example, the ARA asserts, "that bald eagles have excellent eyesight and maneuverability, and are expected to see the turbines and avoid them," but the USFWS letter points out that the ARA statements about the ability of eagles to see and avoid the turbines are without substantiation.

The USFWS then refers to documentation that refutes the ARA's unsupported assertion: killings of white-tailed sea eagles, very close relatives of bald eagles, have been cited in the literature dealing with turbine risks to birds.

The USFWS letter insists that an adequate preconstruction study would consist of data taken from three years of site-specific investigations including attention to both resident and migrant bald eagles and their use of the project area during and outside of the breeding season. The investigations should include site-specific attention to both adult and young bald eagles. The three-year preconstruction study also should be appropriately coordinated with the USFWS and the New York State Department of Environmental Conservation.

Letter regarding the ARA's treatment of all resident and migrant birds

The USFWS letter that addresses the ARA's treatment of all migrant and resident birds includes a brief description of the service's approach to enforcing provisions of the Migratory Bird Treaty Act (MBTA), including the killing or injuring of birds covered by the act. The letter states that, although the MBTA does not permit the incidental taking of protected birds that might be killed by wind projects, the USFWS may "exercise enforcement discretion," targeting enforcement only "on those individuals, companies, or agencies that take migratory birds with disregard for their actions and the law, especially when proceeding without adequate preconstruction study (emphasis ours). . . ." The USFWS then goes on in more than 40 detailed pages to specify why the ARA constitutes an inadequate preconstruction study.

The letter argues that the ARA's base-line data is inadequate, the ARA's reliance on information from other sites around the world has limited application, its risk assessment methodology is not acceptable, and its interpretation of State and federal regulations is misleading and incorrect. The letter also points out that the ARA does not incorporate recommendations made by the USFWS earlier in the coordination process and that the conclusions of the ARA are not supportable by the USFWS.

Among other actions the USFWS recommends are the completion of three-years of comprehensive data collection at the site; the use of radar studies throughout the entire migration period, covering seasons not sampled by the ARA and including critical times of the day excluded from the ARA; and the adoption of a more acceptable risk assessment method "which would likely produce more reliable results." Finally, the USFWS finds that the ARA "did not convince us that putting turbines in a documented avian migratory pathway and in listed species habitat is prudent."

The USFWS letter discusses the need to clarify the potential involvement of the Army Corps of Engineers. The developer has ignored repeated requests from the USFWS to submit materials that could be used to determine whether federal permits will be required from the corps pertaining to any streams or wetlands under federal jurisdiction.

The developer also has ignored the USFWS recommendation to evaluate the proposed project's potential impact on bats. Rather than perform a site-specific evaluation of the risk the project poses to bats, the developer stated that an evaluation would be completed in the environmental impact statement based on a review of existing literature. The USFWS finds this unacceptable

because of the lack of information on birds in Western New York.

Serious problems with the collection of base-line data in the ARA are discussed by the USFWS, specifically the inadequacy of using marine radar alone without corroborating techniques. The USFWS letter concludes that radar coverage was inadequate both temporally and spatially. The USFWS also cites the ARA radar study's confusion about targets, lack of information during poor weather, questions about filtering techniques, and the likelihood of the study's missing the migration peak. The USFWS feels the radar study might have missed nearly half the raptor migration. Despite the fact that the data collected by the radar study is inadequate for drawing conclusions about avian use of the site, USFWS observes that the radar study reported that "the number of spring diurnal migrants is higher than any other location studied in New York State."

The USFWS also addresses some of the standard wind industry arguments the ARA repeats, including comparisons of turbine mortality to other sources of mortality favorable to the wind industry, the need to decrease pollution associated with fossil fuels and the need to decrease our dependence on foreign oil. The USFWS characterizes the comparison of mortality caused by turbines to mortality caused by other sources as unscientific. The USFWS acknowledges that "buildings, cars, power lines, and communication towers kill far more birds than wind turbines" but points out that the number of deaths per unit from sources other than turbines is not known, so meaningful comparisons cannot be made. The USFWS also observes that wind power can only provide a very small percentage of electric power and points out that "Due to the intermittent nature of wind-generated electricity, none of the existing coal, oil, or nuclear powered generation facilities will be shut down or run as reserve units." The USFWS also observes that operating changes currently under way at existing power plants, "will be more effective at reducing emissions than constructing thousands of wind turbines across the landscape."

The USFWS concludes that they cannot "agree with the ARA report's conclusions or the basis for them" and questions the placement of a turbine project in a migration flyway. In questioning the proposed placement of this project, the USFWS points out a number of environmental groups that question placing turbines in areas where birds congregate or migrate, observing that even the American Wind Energy Association, advocates of wind power, recommend against "placing structures in bird concentration areas, especially where threatened and endangered species are found."

May 15, 2006

Dear School Board Members:

My name is Glenn Fountain and I currently reside in Plattsburgh. My wife Faye and I highly support the proposed Marble River Wind Farm. We are land owners in Churubusco having 430 acres, and our intentions are to be a residents upon my retirement which is 18 months from now. We believe that taking advantage of future resources for the community would be beneficial all around. Creating jobs, royalties, tax payments, etc. in our community of Churubusco, would be a big step in the right direction. With the price of fuels, rising every day WIND as an alternative power source is the way the people of the United States must go. We are too dependent on foreign countries for our fuel resource. Respectfully with all the hard work and time the board has put forth, I hope you make the right decision and go ahead with the Wind Farm project. This would also benefit our children and grandchildren with future energy and pollution problems.

Sincerely, *Glenn Fountain Sr.*

Faye Fountain

Glenn Fountain Sr.

Faye Fountain

15 May 06

Supervisor Jim McNeil,

Dear Jim,

We strongly support the wind farm projects proposed for Ellenburg.

I have observed wind generators in Canada, foreign countries and other places in New York. My observation lead me to conclude that the noise level is not objectionable, and that it is almost non-existent and the view is no more objectionable than the high electric wires and other man made objects.

I hope the Town Board will consider the economic benefits of these projects.

Dear Jim:

I enjoyed talking to you the other morning at Filini's Restaurant. I just wanted to say that I am in favor of the Wind Program in Ellenburg. I have 80 acres on the Plank Road and am a taxpayer in town.

I believe this project would be a tremendous boost to the community and might help us all with tax department.

We are fortunate to have such a clean + abundant commodity - Wind.

Sincerely

Dr. Anthony C. Cassani AD

Kevin Hollister, President

At its regular meeting on May 11, 2006 the Clinton County Farm Bureau Board of Directors passed a resolution concerning the establishment of commercial wind power projects.

The resolution reads: *Be it resolved that the Clinton County Farm Bureau fully supports the establishment of commercial wind turbines on our member's farms.*

This resolution is intended to support those farmers who wish to participate in the projects being proposed for their property.

This is in keeping with the policies of New York Farm Bureau and American Farm Bureau Federation which support and encourage the establishment of renewable energy sources, including wind, solar and bio-fuels.

Town of Ellenburg DEIS hearing regarding Noble Environmental Power's request for permit to erect a wind farm project.

Good evening my name is Kirby Selkirk. I'm a Field Advisor for New York Bureau and I'm here on behalf of Clinton County Farm Bureau.

At its regular meeting on May 11, 2006 the Clinton County Farm Bureau Board of Directors passed a resolution concerning the establishment of commercial wind power projects.

The resolution reads: *Be it resolved that the Clinton County Farm Bureau fully supports the establishment of commercial wind turbines on our member's farms.*

This resolution is intended to support those farmers who wish to participate in the projects being proposed for their property.

This is in keeping with the policies of New York Farm Bureau and American Farm Bureau Federation which support and encourage the establishment of renewable energy sources, including wind, solar and bio-fuels. I've included a copy of their statement for you.

Environmentally, the turbines are great for farmers – you can crop or pasture right up to the turbine and the development company takes great care in restoring the farmland impacted by construction. At the end, there is only a road that leads to the turbine.

This project and others could provide 6% of our nation's electricity, or about the same as hydropower, by 2020. A New York study found that if wind energy supplied 10% (3,300 MW) of the state's peak electricity demand, 65% of the energy it displaced would come from natural gas, 15% from coal, 10% from oil, and 10% from electricity imports. As many as 215,000 new jobs would be created by adding 50,000 MW of new wind installations in the U.S. - a \$50 billion investment that could provide electricity for as many as 15 million homes with 39 million people.

Last year wind energy generated over 17 billion kilowatt-hours in the U.S., enough electricity to power 1.6 million homes. A single wind turbine can provide \$4,000 - \$7,000 each year in farm income and only use 2-5 percent of the land for the turbine and access road. Each megawatt (MW) of wind energy capacity installed in the U.S. provides 2.5-3 job-years of employment. In 2006, U.S. wind farms will be saving over 0.5 billion cubic feet of natural gas per day. To generate the same amount of electricity as a single 1-megawatt (MW) wind turbine, a traditional fossil fuel or nuclear power plant requires, on average, withdrawing about 60 million gallons of water per year from a stream or river. To generate the same amount of electricity as today's U.S. wind turbine fleet (6,740 MW) would require burning 9 million tons of coal (a line of 10-ton trucks 3,437 miles long, from Seattle to Miami) or 28 million barrels of oil each year.

I have prepared a list of the New York Farm Bureau policies pertaining to the siting and construction of energy facilities. These address our concerns of protecting the farmland. I will cite only one.

When siting utility right-of-ways, adverse agricultural effects on all farms should be minimized by:

), judicious routing to help avoid construction and operation through farmsteads, croplands, orchards, and sugarbush

operations;

b. Utilization of state-of-the-art mitigation practices and full rehabilitation of all agriculture-related lands which are not otherwise avoided;

c. Utilization of qualified agricultural specialists to maintain on-going field contact with all affected farmers and other organizations from project design stage through final land rehabilitation;

NYSDAM has qualified personnel whose job it is to do this work and their involvement should be included in local regulations governing the construction of any such projects

d. Ensuring just compensation for right-of-way easements and damages; and

e. Consideration of all other viable routing options with preference being given to the use of previous utility right of ways and highway medians.

I will submit written copies of this our policies and the resolution from Clinton County Farm Bureau

Kirby Selkirk
Field Advisor
New York Farm Bureau
POB 902
Chateaugay NY 12920

Policies of New York Farm Bureau regarding the siting of energy facilities on agricultural land

We encourage the development of more energy from wind and solar power sources.

We recommend companies with rights-of-ways on farmland identify the location of their underground transmission lines and/or pipelines.

When siting utility right-of-ways, adverse agricultural effects on all farms should be minimized by:

a. Judicious routing to help avoid construction and operation through farmsteads, croplands, orchards, and sugarcorn operations;

b. Utilization of state-of-the-art mitigation practices and full rehabilitation of all agriculture-related lands which are not otherwise avoided;

c. Utilization of qualified agricultural specialists to maintain on-going field contact with all affected farmers and other organizations from project design stage through final land rehabilitation;

(NYSDAM has qualified personnel whose job it is to do this work and their involvement should be included in local regulations governing the construction of any such projects)

d. Ensuring just compensation for right-of-way easements and damages; and

e. Consideration of all other viable routing options with preference being given to the use of previous utility right of ways and highway medians.

Productive farmland or aquaculture/fishing grounds should not be taken by eminent domain for the construction of a power generation plant nor should this plant's location negatively impact neighboring productive farmland or aquaculture/fishing grounds.

Public utilities should be required to investigate all complaints of stray voltage on farms within (five (5) working days. The utility

should be required to isolate or place a blocker on grounded lines if it is found that the utility system is imposing a voltage onto the customer system at a level at or above known levels of concern.

We support an amendment to the current Dig Safe New York Law 16NYCRR, Part 753 to read: "All utilities will be buried a minimum of (48") forty-eight inches deep and that Dig Safe NY will verify this with a letter to each agricultural property owner who has utilities crossing their property, and that it will relieve any responsibility from the owner if the utilities are disturbed".

We recommend that priority should be given to projects promoting naturally renewable sources of energy. Assistance from government (such as NYSERDA) for such projects should be prioritized. Local governments should receive incentives from the state and federal government for promoting such projects locally.

We support property tax exemptions for those farms that have solar or wind energy systems or farm waste energy systems.

All aspects of agriculture should equally be eligible to participate in government programs meant to protect the environment and/or conserve energy.

Wind towers should be allowed on private property.

October 06, 2005

Mr. Francis LaClair
7741 Star Rd.
Ellenberg Ctr, NY 12934

Dear Mr. LaClair:

Thank you for supporting the development of wind energy in New York State by purchasing 2 blocks of New Wind Energy[®] per month for a total of 24 blocks per year. Your purchase enables NYSEG to arrange for the delivery of 2,400 kilowatt-hours per year of wind-generated electricity into the New York State power grid.

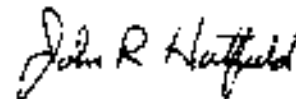

NYSEG and Community Energy, Inc., (CEI) are pleased to give New York consumers the opportunity to purchase electricity generated from new wind farms in New York. Now, for the first time, New Yorkers are directly influencing how electricity is generated in the state, and we're pleased to see customers like you making a difference. Electricity produced by naturally occurring wind requires no fuel and produces no emissions. The environmental benefits of your purchase equate to a reduction of 8 pounds of sulfur dioxide (SO₂) emissions, and 3 pounds of nitrogen emissions annually. In terms of reduced carbon dioxide (CO₂) emissions, this is equivalent to not driving 2,338 miles per year, or planting 146 trees.

At the end of each year, you will receive a certificate indicating the number of kilowatt-hours of wind generated electricity delivered to the New York grid on your behalf. Using the New York State Public Service Commission tracking system, we will send you an environmental disclosure label describing your contribution to air quality. If you obtain your electricity supply from a supplier other than NYSEG, information about your purchase will be forwarded to them for environmental disclosure purposes.

Enclosed are the **Terms and Conditions** that govern your purchase. Please read them carefully and let us know immediately if you have any concerns or questions.

Again, thank you for your commitment to renewable energy and the development of wind power in New York State. If you have any questions, please call us at 1-800-356-9734.

Very truly yours,

John R. Hatfield
Program Manager

December 16, 2005

Important Wind Program Update

Mr. Francis LaClair
7741 Star Rd.
Ellensburg Ctr, NY 12934

Dear Mr. LaClair,

Thank you for your continued support of New Wind Energy through our wind program. Our customers are responsible for reducing toxic emissions from sulfur dioxide by more than 216,000 pounds. Nitrogen emissions have been reduced by almost 59,000 pounds. Environmental benefits are equivalent to not driving nearly 37 million miles, or planting almost 3 million trees each year. The positive environmental impact is very impressive.

Many NYSEG customers have signed up to support wind energy, and we are now nearing maximum capacity for our New York generated wind supply. New wind farms are being built in New York to serve the growing wind demand and they will be on line in 2006. In the meantime, we will be supplying a small part of your annual wind energy purchase from wind farms nearby in Pennsylvania. The only difference you'll see is more wind turbines on the horizon in New York State, thanks to your efforts!

Your participation in the program will continue to be tracked and verified through the NYS Public Service Commission and NYSEG.

Also, we are excited to inform you that during the upcoming year, we will be implementing a new billing system that will include wind charges directly on your regular electric bill. Your total annual wind charge will be divided evenly over 12 months. When the new system is operational and your next payment is due, you no longer will be billed separately for your wind purchase. The new system will cut down on paperwork, postage and time - making your participation in the program easier and more enjoyable. The process will take several months, so check your bill monthly to know when the change is in place.

As always, we're more than happy to answer any questions or concerns about renewable energy, so please give us a call at 1.800.356.9734. Thank you again for your commitment to a cleaner, more secure energy future.

Best regards,

John R. Hatfield
Program Manager

Economic Impacts of Wind Power in Kittitas County

Final Report

A Report for the

Phoenix Economic Development Group

by

ECONorthwest

888 SW Fifth Ave, Suite 1460 Portland, OR 97204 (503) 222-6060

November 2002

Acknowledgements

This report was prepared by ECONorthwest's Portland office for the Phoenix Economic Development Group of Ellensburg, WA. Dr. Stephen Grover was the ECONorthwest project manager for this analysis and was the primary author of this report. Questions regarding this report should be directed to him at grover@portland.econw.com or by phoning the Portland office at (503) 222-6060. Dr. Grover was assisted in this project by Anne Fifield, Alec Josephson, and Bob Whelan.

This report was funded by the State of Washington Office of Trade and Economic Development and the Energy Foundation.

The Economic Impacts of A Proposed Wind Power Plant in Kittitas County, WA

An Evaluation of Potential Impacts on Property Values, Tax

Revenues, and the Local Economy

f. Introduction and Summary

Two different wind energy companies are currently developing plans for constructing and operating wind power turbines in Kittitas County. The energy company Zilkha Renewable Energy has proposed a project with 110 wind turbines that have the combined potential to generate approximately 165 megawatts of electricity during peak wind periods. A second company enXeo is proposing building 150 additional wind turbines with a total of 225 megawatts of generation potential. These two projects combined would involve the construction and operation of 260 wind turbines with a potential generating capacity of 390 megawatts of electricity.

As part of the planning process for these projects, the Phoenix Economic Development Group has hired ECONorthwest to evaluate the potential economic impacts of constructing and operating the wind plants in Kittitas County. Specifically, ECONorthwest was asked to analyze and help quantify impacts in three key areas of interest:

- **Property Values.** Local residents have voiced concern that constructing numerous wind turbines in the valley will detract from views and ultimately reduce property values.
- **Economic Impacts.** The wind plants will create jobs and increase spending in the economy during the construction phase and during plant operations.
- **Tax Revenues.** The increase in jobs and local spending will also increase tax revenues for Kittitas County.

To research these issues, we utilized several different analysis techniques. We surveyed tax assessors in other counties with wind projects to determine the potential effects of wind farms on property values. We also conducted a review of the available academic literature for additional information on property value effects. Local economic impacts were estimated using an input-output model based on construction and operations data obtained from the two companies proposing wind projects in Kittitas County. Tax revenues were estimated from the input-output model results based on tax rate and spending information obtained from Kittitas County.

Our analysis in these areas has resulted in the following key findings:

- *Views of wind turbines will not negatively impact property values.*
Based on a nation-wide survey conducted of tax assessors in other areas with wind power projects, we found no evidence supporting the claim that views of wind farms decrease property values.
- *Wind plant construction will have significant economic benefits.*
The construction of over 250 turbines will create approximately 185 full and part time jobs in Kittitas County and will increase total income to the county by over \$12 million during the construction period.
- *Wind plant operation will provide additional annual economic benefits.* The wind farm operations will require 53 additional jobs and will increase income to the county from salaries and operations expenses by over \$4 million annually.
- *Property tax revenues will increase.* The construction of the wind farm will increase property tax revenues collected in the Kittitas County by approximately \$2.8 million dollars annually.

- an increase of 11 percent over current property tax revenues. The majority of this increase is due to the property tax paid on the wind turbines.

- *Tax revenues to Kittitas County Government will also increase.* Tax revenues accruing directly to Kittitas County Government will be approximately \$693,000 annually. This increase results from the County's share of new property tax revenue and from increases in other taxes.

Details on the analysis underlying each of these results are presented in the remainder of this report.

II. Property Value Impacts

One of the biggest concerns of the community is that the installation of numerous wind turbines will detract from the current viewscape in the Kittitas Valley and that the destruction of this view will ultimately reduce residential property values.

We conducted two separate analysis tasks to address this issue. First, we conducted a phone survey of tax assessors for counties that recently had wind turbines installed in their areas. In addition to interviewing tax assessors, we also reviewed the current literature for statistical studies that quantified the impact of wind turbines on property values. For comparison purposes, we also reviewed the literature on the impact that transmission lines have on property values.

A. Tax Assessor Interviews

The first step in our survey of tax assessors was to develop an appropriate sample of sites for the analysis. These sites were chosen using the following criteria:

- *Projects constructed within the last 10 years.* Recently completed projects were used to ensure that reliable information was obtained from the assessor. Recent sites are also more likely to have the same turbine technology that is planned for Kittitas County.
- *View locations.* As much as possible, we attempted to find wind farms that could be seen from residences rather than focusing only on sites in remote or very rural locations.
- *Multiple turbines.* We focused on those areas where multiple turbines were installed to be comparable with the projects proposed for Kittitas County.

We applied these criteria to information obtained from the American Wind Energy Association website to locate candidate wind projects in areas throughout the U.S. Table 1 shows descriptive information on 19 projects we located using this method.

Note: * Number of turbines estimated by E.ON Northwest based on reported MW capacity.

In addition to the sites shown in Table 1, we also added projects in Alameda County, California, Walla Walla County, Washington, and the Town of Lincoln, Wisconsin as they all contain wind projects that are similar to that proposed for Kittitas County. The final sample included 22 wind projects located in 13 different counties throughout the country.

Once the sample was determined, the next step was to interview tax assessors within each county to determine the effect these projects had on residential property values. We chose to interview assessors as they are required to provide objective assessments of property values. If assessments are perceived to be too high by the landowners, the assessed value may be challenged in court. Unlike real estate agents, who have a financial stake in the market values of properties they sell, tax assessors do not have an incentive to inflate property values or to exaggerate the possible effects of wind turbines. For these reasons, we chose to interview tax assessors as they are the best available source for unbiased information on the effects of wind turbines on property values.

From our initial target sample, we were able to interview assessors from all thirteen counties. Based on these interviews, we found no evidence indicating that views of wind turbines decreased property values. Of the counties we interviewed, six contain residential properties with views of the wind turbines, and six counties lack residences with a view of the turbines. One county reported that the wind farm is too new for the assessor's office to know if nearby property values have been affected.

Six counties reported that residential properties have views of the wind turbines, but the turbines have not altered the value of those properties. Responses from assessors in these counties were similar:

- Kern, California—Residents are able to see the turbines from many locations within the town of Tehachapi. The views of the wind turbines have not affected the assessed values of these residences.
- Lincoln, Minnesota—The turbines are located about two miles outside of town. The turbines do not block the view of any particular feature, but residents can see them if they look for them. The assessor hasn't heard anyone complain about the turbines' appearance. Some residences located in the rural parts of the county have closer views of the turbines, but the turbines have not impacted their land values.
- Buena Vista, Iowa—Many residences in the towns of Alta and Storm Lake have views of the turbines. The turbines are easily seen from town, they are located a couple of miles

outside of town, and sit on a high ridge. There has been no impact on land values.

- Howard, Texas—There are no homes within two miles of the wind turbines, but because the terrain is so flat, the turbines are visible from as far as 25 miles away. Appraised land values have not declined because of views of the turbines. The appraiser reported that their office expected property owners to complain about lowered property values caused by a diminished view, but so far they have received no complaints.

- Walla Walla County, WA—The turbines are on a high cliff that has a lot of wind and low land values. The unincorporated town of Touchet lies about 8 miles from the turbines and some residents do not like the views of the turbines as it affects their view of the sunset. This factor has not translated into lower land values according to the assessor. Touchet's tax base rose from just over \$100 million to \$265 million with the

addition of the wind farm and resulted in the addition of 20 to 25 permanent local jobs according to the assessor.

- Town of Lincoln, Wisconsin—The assessor reported that when the turbines were first installed, residents complained about the diminished view. However, in the three years since installation, residents have become used to them, and no one complains now. One homeowner had claimed that the assessed value of his property should be reduced because of the wind turbines. The County asked him to show that the value of sales of properties near the turbines had diminished, and he was unable to do so.

To investigate further the potential impacts on property values, Lincoln's assessor compared the 2001 assessed value to actual sales (for arms-length transactions of residential properties) and found that the ratio of assessed values to actual sales prices for properties less than one mile from the wind turbines was no greater than for properties more than a mile from the wind turbines. The assessor noted that the wind turbines had negatively impacted television reception for nearby properties, but the utility company provided the impacted homes with better antennas or a satellite dish to bring reception back to previous levels.

The wind farms have had no impact on neighboring property values in five counties as neighboring properties are in agricultural production. Assessors' offices in Alameda, California, Carbon, Wyoming, Crockett and Culberson in Texas, and Umatilla, Oregon reported that no residential properties have views of the wind farms. The neighboring properties are grazing land, and the value of the land is determined by its productivity, not its views. For Riverside County, California, the wind farm was built along the freeway with a buffer zone to separate it from residences. Consequently, very few homes have a view of the turbines in that county and the assessor reports that there has been no impact on property values. Nobles County, Minnesota reported that the wind farm in the county was installed in the past year, and it is too early to determine if they have affected neighboring property values.

One county reported that land parcels with wind turbines located on them have changed in value. Kern County, California reported that property eligible for a wind turbine greatly increases in value. The first step to siting a wind turbine is to change the land from a grazing zone to a "wind energy" zone. By changing the zone, the land value increases from about \$300 to about \$1000 per acre. No other county reported such an impact to land values.

Wind farms in two counties, Howard in Texas and Umatilla in Oregon, have added to the tax base. The assessors' offices reported that the wind turbines are large capital improvements, and they have contributed to the tax base. This was not a specific question in the interview, and these two counties volunteered the information. The same is likely true in other counties, but the issue was not pursued during the assessor interviews.

Representatives from three assessors' offices reported that community members like the appearance of the wind turbines. The appraiser in Kern County speculated that residents like the appearance of the wind turbines as long as the turbines are functioning. The turbines that were built in the early 1980s had a high failure rate, and many of the turbines just sat on the property in disrepair. That experience led many to feel that wind farms are an eyesore. The newer turbines have a very low failure rate, and residents can see the turbines are operating and creating an economic good, which positively impacts their perceptions of the turbines.

In Kern County, some residents located on rural properties complained about the plan to locate wind turbines near their properties. They argued that they had bought their properties with the expectation of a view of grazing land, not a wind farm. To solve the problem, the wind developer paid them for the property and the people moved. The wind developer then sold the property, although the property values did not decrease.

B. Literature Review

The results of the tax assessor interview show that views of wind turbines do not negatively impact property values. In addition to these interviews, we also conducted a literature review to determine if other studies had found credible evidence of a negative impact on property values. We restricted our literature review to academic journals that only publish articles that have been subjected to a peer review process. References for the articles we reviewed are included in Appendix B of this report.

We found only one study that specifically addressed the potential impact of wind turbines on property values and this study was based on residential property in Denmark. The hedonic study showed that house values were lower close to wind farms than other houses located further away but with otherwise similar characteristics. This result was based on a small sample of homes, however, and the difference in home price was not statistically significant.

One of the likely reasons that wind turbines do not diminish property values is that not all people agree that views of wind turbine are undesirable. As reported by the tax assessors, some residents find views the wind turbines attractive. If a homeowner dislikes having a view of the wind farm, they may move and sell their house to someone who likes the view. In this case, property values would not be diminished.

We also reviewed the academic literature addressing transmission lines and their impact on property values. Unlike wind turbines, transmission lines are almost universally considered unattractive. There is also widespread belief that living near transmission lines is a health hazard. For these reasons, there is a much clearer case that transmission lines will negatively affect property values. Legal cases have agreed that the public perception of danger or health risk can impact property value, regardless of the reasonableness of the public's fear (Rakon 1996).

It is important to emphasize the purpose of reviewing the literature on transmission lines for this analysis. Our review of the literature on transmission lines was done solely to provide an indication of the maximum negative effect views of wind turbines might have on property values *if such a negative impact exists*. As we have indicated from our assessor interviews and literature review, we have not found any evidence that views of wind turbines have any effect on property values. Nevertheless, the information from the literature on power lines is informative.

The evidence from the literature on transmission lines shows that their effect on property values is

small and relatively short-lived. The maximum impact on adjacent properties due to transmission lines is about a 10 percent reduction in value. Many studies use hedonic estimation techniques to measure the impact transmission lines have on property values while controlling for other features of the homes. The most recent study (Des Rusiers, 2002) found a severe visual encumbrance due to a direct view of a transmission line pylon does exert a negative impact on property prices. Overall, the price reduction stands at roughly 10 percent of average house value. However, being adjacent to the easement will not necessarily cause a house to depreciate. It may even increase its value where proximity advantages (enlarged visual field, increased privacy) exceed drawbacks. Additionally, findings for the non-adjacent properties that have views of the power lines translates in most cases into higher values, due to the improved visual clearance.

Some earlier studies agree that transmission lines have a slight negative impact on property values. Hamilton (1995) found that properties adjacent to a line lose 6.3 percent of their value due to proximity and the visual impact. Properties more distant from transmission lines are scarcely affected, losing roughly 1 percent of their value. Delaney and Tammons (1992) found that, generally, real estate appraisers believe that transmission lines reduce the value of nearby residential properties by 10 percent. The authors' survey found that 84 percent of the surveyed appraisers believed transmission line have a negative impact, 10 percent believed that there is no impact, and 6 percent believed that there was a positive impact on property values. Colwell (1990) found that properties within 50 feet of an EHV1 have a 6 percent to 9 percent lower value than comparable properties, but that drop in value lessens over time and tends to fade away.

As the literature indicates, the negative effect on property values due to transmission lines is 10 percent or less, with this effect diminishing over time. This is reported only for comparison purposes for the case of wind turbines. Again, information from tax assessors and the literature indicate that views of wind turbines do not negatively affect property values.

III. Local Economy

A second component of our analysis addressed the economic impact of the wind turbines on the Kirtiras County economy. We interviewed representatives from both Zilkha and enXeo to determine the amount of spending and employment for the proposed projects. Using this information, we used a regional 'input-output' model with data specific to Kirtiras County to estimate the economic impacts of the project. We used our model to estimate the economic impacts for both the construction phase and the operations phase of this project. Details on both these phases are reported below.

A. Construction

The construction of 260 individual wind turbines will involve a significant amount of employment and spending during the construction period. We have talked to representatives from both Zilkha and enXeo to determine the likely employment and construction spending. Based on these conversations and our experience analyzing similar projects we developed estimates for use in our model. Our input parameters for the construction phase included:

- 85 full and part time local construction jobs
- 10 full and part time jobs for wind company and utility personnel to manage the plant construction phase

- \$6,400,000 in local spending on construction materials (i.e., gravel, concrete)

- \$886,000 in spending on food and lodging for non-local labor brought to Kittitas County for the construction period

Based on these and other input parameters, we estimated the impacts to the local economy for a construction period predicted to last approximately one year.

For the input-output model, economic impacts are grouped into three different categories.

- **Direct economic impacts.** Businesses directly purchase goods and services in their local economies. An increase in spending, therefore, affects the economy directly through increased purchases.

- **Indirect economic impacts.** Businesses also indirectly affect local economies, as those firms that provide direct services to the wind project must also purchase materials and supplies themselves. For instance, a construction contractor working on this project will lease some equipment or purchase supplies locally. Increased purchases of “intermediate” goods and services will also promote additional economic activity.

- **Induced economic impacts.** The direct and indirect effects of employment and income affect overall economy purchasing power, thereby affecting further consumption spending. For instance, wind plant employees who use their income to buy groceries or take their family to the movies generate economic impacts for workers and businesses in those sectors. These individuals will, in turn, spend their income much like the wind plant employees do. This cycle continues until the spending eventually leaks out of the local economy as a result of

taxes, savings, or purchases of non-locally produced goods and services or “imports.”

In addition to these categories, economic impacts are also divided into different income effects. In the following tables, the impact on *Wages* reflects the increase in wage income for all workers as a result of the project. Similarly, *Business Income* is the increase in income to local business as a result of spending associated with the wind plant. *Personal Income* is the sum of wages and business income. The *Other Income* category is used to capture additional income that results from other sources due to the project, such as rents to land owners leasing land for wind turbines. Finally, *Jobs* reflects the number of full and part time jobs that result directly from the project and from the increase in spending in other sectors of the economy.

Additional technical detail on the input-output model is included in Appendix A of this report.

The following tables show the economic impacts for the construction period.

Table 2: Construction Phase Economic Impacts for Kittitas County

Impact type	Wages	Business Income	Personal Income	Other Income	Jobs
Direct	\$8,420,000	\$1,027,000	\$9,447,000	\$388,000	95.2
Indirect	732,000	139,000	871,000	242,000	30.3
Induced	1,050,000	225,000	1,275,000	234,000	60.0
Total	\$10,202,000	\$1,391,000	\$11,593,000	\$864,000	185.5

As shown in Table 2, the construction phase of the project will result in approximately 95 full and part time jobs. Spending from this project on labor and materials will result in an additional 90 jobs for a total of approximately 185 full and part time jobs during the construction period. Wages during this period will be \$10,202,000 due to the hiring of local construction workers and the increases in services needed to support the construction work. Similarly, business incomes will increase by \$1,391,000 due to spending on local materials and other items such as food and lodging for non-local labor hired for the project. Taken together, personal income is estimated to increase by \$11,593,000 in Kititas County due to spending during the construction phase. When the income of \$864,000 from other sources is considered, the increase in income to the county totals \$12,457,000.

Table 3 provides the same information broken out by industry sector. Most of the spending during this phase occurs in the Construction sector. Sectors that will support this sector such as the Wholesale and Retail Trade and Services sectors will also see a significant increase in spending.

Table 3: Construction Phase Economic Impacts by Industry

Industry	Wages	Business Income	Personal Income	Other Income	Jobs
Agriculture, Forestry, and Fisheries		\$7,000	\$44,000	\$15,000	1.7
Construction	7,979,000	\$1,044,000	\$9,022,000	\$369,000	90.4
Manufacturing	42,000	\$4,000	\$46,000	\$16,000	1.4
Trans., Comm., & Utilities	778,000	\$44,000	\$812,000	\$57,000	9.7
Wholesale and Retail Trade	611,000	\$56,000	\$667,000	\$90,000	36.2
Finance, Insurance, & Real Estate	66,000	\$29,000	\$95,000	\$120,000	3.5
Services	618,000	\$218,000	\$836,000	\$146,000	41.2
Government	71,000	\$0	71,000	\$31,000	1.3
Total	\$10,202,000	\$1,391,000	\$11,593,000	\$864,000	185.5

Note: Totals may not match due to rounding

B. Operations

Spending will continue in the local economy during the operation of the wind turbines once the construction phase has ended. During the operations phase, spending will consist of primarily:

- 22 employees hired to operate and manage the wind power plants
- Spending on equipment, maintenance and materials to operate the wind turbines
- Income to property owners that rent land for the wind turbines (\$4,500 per turbine.)

The impact to the local economy due to the wind plant operations was modeled based on these factors. As during the construction phase, there is a direct effect from these factors as well as an indirect effect that results from the spending due to the increases in income from the new jobs and from the rental income. These impacts are summarized in Table 4 and Table 5.

Table 4 shows the effect on incomes due to continued operations of the wind turbines. The operations will require 22 full and part time jobs, and the spending on these jobs and plant equipment will create approximately 31 additional jobs in businesses that support the wind plants. The combined effect of direct and indirect spending will result in approximately 53 additional new and part time jobs in Kittitas County. Similarly, spending on these jobs will increase annual wages by \$2,728,000 and yearly business income by \$351,000. Income from other sources is estimated at \$1,188,000 annually and will consist primarily of rental fees paid to land owners where the wind turbines are situated. Taken together, the wind turbines operations will increase income to the county by \$4,267,000 annually.

Table 4: Wind Plant Operations Annual Economic Impacts for Kittitas County

Impact type	Wages	Business Income	Personal Income	Other Income	Jobs
Direct	\$2,165,000	\$218,000	\$2,381,000	\$819,000	22.0
Indirect	77,000	30,000	107,000	22,000	3.1
Induced	486,000	105,000	591,000	347,000	28.2
Total	\$2,728,000	\$351,000	\$3,079,000	\$1,188,000	53.3

Table 5 shows the economic impacts resulting from wind turbine operations broken out by industry sector. Most of the impacts will be in the Transportation, Communications, and Utilities sector. The Real Estate and Service sectors will also see increased economic activity due to the continued operation of the wind farm.

Table 5: Annual Wind Plant Operation Impacts by Industry

Industry	Wages	Business Income	Personal Income	Other Income	Jobs
Agriculture, Forestry, and Fisheries	\$10,000	\$1,000	\$11,000	\$4,000	0.5
Construction	63,000	29,000	92,000	4,000	2.6
Manufacturing	11,000	1,000	12,000	5,000	0.4
Trans., Comm., & Utilities	2,190,000	226,000	2,416,000	27,000	22.7
Wholesale and Retail Trade	211,000	19,000	230,000	76,000	13.3
Finance, Insurance, & Real Estate	29,000	12,000	41,000	1,012,000	1.5
Services	185,000	64,000	249,000	35,000	11.8
Government	29,000	0	29,000	25,000	0.5
Total	\$2,728,000	\$351,000	\$3,079,000	\$1,188,000	53.3

Note: Totals may not match due to rounding

IV. Tax Revenues

The overall increase in economic activity from the wind power plant will increase tax revenues for Kittitas County. ECONorthwest was asked to estimate the impact on tax revenues for the major sources of tax income for the county. Note that we did not attempt to estimate the increases in costs or the provision of county services (i.e., fire, sheriff) that the wind power plant might require.

Based on our review of Kittitas County budgets and spending and our evaluation of the proposed wind power facility, we have estimated the potential revenue impacts for the Kittitas County. Table 6 shows the estimated increases in revenue for the major tax revenue sources.

As shown in Table 6, the primary increase in tax revenues is from property taxes on the wind turbines themselves. For this calculation, we have valued each turbine at approximately \$765,000, which is consistent with our experience in other wind projects and with the information provided to us by the wind companies involved with the Kittitas County project. The property tax rate used for the calculation is 1.35 percent for Kittitas County. Given these parameters, for the proposed 260 turbines we estimate new property tax revenues of \$2,683,125 annually.

The development of this project will also have an effect of increasing the value of other properties due to the increase in wages and overall economic activity in Kittitas County. This results in an additional \$201,971 in property tax revenues annually due to increases in other property values.

When the property tax revenues from both sources are combined, the additional tax revenue collected within Kittitas County totals \$2,885,096 annually. For comparison, property tax revenues from all sources in Kittitas County totaled \$25,223,948 for the 2001-02 budget year. The increase in property tax revenues due to the wind farm amounts to an increase of 11 percent over these levels.

Table 6: Increases in Annual Property Tax Revenues in Kittitas County

Revenue Source	Amount
Property taxes on wind farms	\$2,683,125
Taxes from higher values on other properties	201,971
Total	\$2,885,096

A complicating factor in these revenue estimates is the recently passed Initiative 747 (I-747) in Washington State, which limits increases in tax levies to 1 percent a year. From our conversations with the Kittitas County assessor and from information provided by Washington State, it appears that most of the value of a wind turbine (\$500,000) would be considered personal property and as such would be subjected to this limit. For Kittitas County, total personal property is assessed at \$2,355.4 million. The addition of 260 windmills with a personal property value of \$500,000 each would add \$132 million to the total property value of the county - an increase of 5.5 percent. Since this increase is greater than 1 percent, it is possible that taxes in other areas would need to be reduced in order to comply with I-747. This might involve decreases in personal property tax rates and/or bond levies. It should be stressed that ECONorthwest is not an accounting firm, and the implication of I-747 is discussed here only as one possible scenario based on preliminary tax estimates. However, the tax revenue estimates provided here should be viewed with I-747 in mind, as actual.

Approximately 30 percent of the turbines are to be built on land managed by the Washington Department of Natural Resources rather than on private land. For these turbines, the rental fee for land will be paid to the State, which then returns these funds to schools throughout the state based on district need. At the annual rental rate of \$4,500 per turbine, this amounts to an additional \$351,000.

Kittitas County Assessor's Report 2001 Assessed Valuations Levies and Taxes to be Collected 2002, page 4.

revenues may ultimately be reduced in the County in order to comply with the initiative.

Table 7 shows the likely distribution of the new tax revenues based on the spending allocations reported in the 2002 Kittitas County Budget. This information is also presented graphically in Figure 1.

Table 7: Allocation of Property Tax Revenues

Spending Category	Amount
Local schools	\$874,761
State schools	\$807,538
Fire districts	\$171,952
Local communities	\$240,617
County roads	\$291,106
County government	\$362,657
Hospitals and other local services	\$136,465
Total	\$2,885,096

Figure 1: Allocation of Property Tax Revenues

Based on current spending patterns, local schools receive the largest share of the tax revenue increase at \$874,761 annually. Following the local schools, state schools would receive the next largest share of revenues at \$807,538 annually. The local county government budget would receive \$362,657 annually, local county roads revenues would increase by \$291,106 annually, and annual funds going to local communities from the county would increase by \$240,617. Finally, annual spending for local fire districts would increase by \$171,952 and funds allocated to hospitals and other services in the county would increase by \$136,465.

The property tax revenue estimates reflect funds that are spent in a variety of sectors, both inside and outside Kititas County. In addition to these property taxes, we estimated the tax revenue that will accrue to the Kititas County Government. This was done by comparing the current tax revenues as a fraction of total economic output for Kititas County with and without the wind farm. Using the results from our input-output model, we estimated the total increase in economic output from the proposed wind plant. Given the increase of output with the project, we estimated the increase in tax revenues assuming that tax rates remained constant. For each individual tax, the increases were generally on the order of 0.2 percent annually.

The estimated increase in annual revenue for the Kititas County Government from these taxes is shown in Table 8. The majority of these additional tax revenues are the property taxes collected for county government and roads. Other sources include smaller taxes such as those collected for fees and services as well as revenue returned to the county by the State. Together, these tax revenues total \$693,777. Given the Kititas County Government expenditures of \$44,312,102 planned for 2002, the additional revenue generated by the wind farm represents an increase of almost 2 percent over the budgeted amount.

Table 8: Additional Kititas County Government Tax Revenues

Spending Category	Amount
Property taxes – County government and roads	\$653,763
Sales and use taxes	\$7,103
All other taxes	\$2,927
Licenses and permits	\$2,094

Charges for services	\$8,509
Fines and forfeits	\$2,138
State collected taxes distributed to County	\$17,244
Total	\$693,777

Kittitas County 2002 Annual Budget, page 15.

V. Alternative Uses

A final analysis issue was to assess the types of additional costs Kittitas County would likely incur with a new residential development. Our understanding is that a residential development as has been suggested as an alternative to building the wind farm, although it is unlikely that such a development would utilize all the land that is currently being considered for the wind project.

For this task, we did not attempt to estimate these costs or the amount of tax revenue that might be generated from such a development. Rather, we are listing areas of increased costs to the County based on our experiences conducting fiscal impact analyses for other jurisdictions.

With a new residential development, additional costs will be incurred for extending utilities and roads to the development, with road construction likely comprising the highest share of costs. Utility-related costs include extending water lines, sewer, phone lines, and power lines to the new development. The utility-related costs are usually paid for by system development charges and if the charges are properly constructed, these services will be cost neutral to the County as they will be paid for entirely by the fees collected. Maintenance of items such as roads, however, will likely increase costs for the County.

Additional cost considerations for Kittitas County will be the extension of all county services to a new development. Affected service areas include fire, sheriff, hospital, libraries, and other community services funded by the County. In order to maintain current levels of service to the new county residences in these areas, additional staff may need to be hired.

If the new residential development is large enough, it may also require that additional Kittitas County government officials be hired to handle the increased workloads in all government areas. For example, the addition of a large residential development may require hiring more staff in the assessor's office or possibly additional teachers for that particular school district.

Appendix A: Modeling Process

Expenditure in the utility sectors and construction sectors affect the Washington economy *directly*, through the purchases of goods and services in this state, and *indirectly*, as those purchases, in turn, generate purchases of intermediate goods and services from other, related sectors of the economy. In addition, the direct and indirect increases in employment and income enhance overall economy purchasing power, thereby *inducing* further consumption- and investment-driven stimulus.

The economic modeling framework that best captures these direct, indirect, and induced effects is called input-output modeling. Input-output models provide an empirical representation of the economy and its inter-sectoral relationships, enabling the user to trace out the effects (economic impacts) of a change in the demand for commodities (goods and services).

Because input-output models generally are not available for state and regional economies, special data techniques have been developed to estimate the necessary empirical relationships from a combination of national technological relationships and county-level measures of economic activity. This modeling framework, called IMPLAN (for Impact Analysis for PLANning), is the technique that ECONorthwest has applied to the estimation of impacts.

The IMPLAN model reports the following economic impacts:

- **Total Industrial Output (output)** is the value of production by industries for a specified period of time. Output can be also thought of as the value of sales including reductions or increases in business inventories.
- **Personal income** consists of the wages and salaries received by households (employee compensation) and the payments received by small-business owners or self-employed individuals (proprietary income). Employee compensation includes workers' wages and salaries, as well as other benefits such as health and life insurance, and retirement payments. Proprietary income, for

IMPLAN was developed by the Forest Service of the US Department of Agriculture in cooperation with the Federal Emergency Management Agency and the Bureau of Land Management of the US Department of the Interior to assist federal agencies in their land and resource management planning. Applications of IMPLAN by the US Government, public agencies and private firms span a wide range of projects, from broad resource management strategies to individual projects, such as proposals for developing ski areas, coal mines, and transportation facilities, and harvesting timber or other resources. ECONorthwest has applied the model to a variety of public and private sector energy projects including a major US/Canada gas pipeline project and the proposed purchase of Portland General Electric by local counties.

- **example, would include income received by private business owners, doctors, accountants, lawyers, etc.**
- **Other property type income (other income)** in the IMPLAN model includes payments to individuals in the form of rents received on properties, royalties from contracts, dividends paid by corporations, and corporate profits earned by corporations.
- **Job impacts** include both full and part time employment.
- **Tax revenues** for various federal, state and local taxing jurisdictions.

Ideally, expenditures for the proposed wind farm would be available and specific enough to allocate to each of the 528 industry sectors contained in the IMPLAN model. In addition, the expenditures should be delineated between local and non-local providers, as purchases of goods and services from out-of-state vendors will have no economic impact on Washington employees and businesses.

In absence of this detailed information, ECONorthwest opted to use the production function data for the utility and government sectors contained in the IMPLAN modeling software. From an input-output modeling perspective, this is a standard modeling approach in the absence of detailed primary source data. Indeed, IMPLAN's production function data contains information, called regional purchase coefficients that describe the proportion of a given commodity that will be provided by Washington producers. Our previous modeling experience has shown that the data contained in the IMPLAN modeling system for the various sectors is sufficient to permit an accurate rendering of impacts.

however, suggesting a more conservative approach to securing the removal of the turbines to provide the Town with the needed confidence in our approach.

Our proposal is to place a surety bond or equivalent financial security instrument on or before the commercial operations date for the facility in the amount of \$50,000 renewable on an annual basis. The security instrument shall include a provision that should another instrument of equal value fail to be placed prior to it's expiration it may be drawn without any other requirement. Bi-annually the values for turbine scrap and removal costs shall be audited and confirmed by an independent third party engineer in a report to the Town Board. Any adjustment in security value recommended by the engineer's report shall be in place within 60 days of the delivery of the report to the board.

Secondly, we further propose to place a larger replacement surety bond or equivalent financial security instrument on or before the fifteenth anniversary of the commercial operations date for the facility. (The year fifteen value of the turbines are still approximately double the estimated cost of removal.) The proposed value for the security would be ten thousand dollars per turbine (a total value which is roughly ten times the expected cost of decommissioning less the scrap value of the turbines as noted in the calculations included herein) or other value to be recommended by the independent engineer in his report the year before.

Revegetation and Reseeding

All Project areas not under cultivation or reserved for some other use by property owners will be revegetated or reseeded, as appropriate.

**February 2006
WECS Removal Cost Analysis**

Removal Costs (per tower):

Remove Tower
 6 Men @ 4 days @ 8 hrs @ \$65 = \$ 12,480.00
 Crane 5 days @ \$2500/day = 12,500.00
 \$ 24,980.00

Remove Concrete to 3' Below Grade
 4 men @ 24 hrs @ \$55 = 5,280.00

Judy Baker

Trackhoe 3 days @ \$1600/day =	<u>4,800.00</u>
	\$ 10,080.00
Remove Roads (1,000' /Turbine)	
2 men @ 3 days @ 8 hrs @ 65 =	\$ 3,120.00
Grader & Loader 3 days @	
\$2,000 =	<u>6,000.00</u>
	\$ 9,120.00
Revegetation and reseeding	\$ 150.00
Sub-Total:	\$ 44,330.00

Scrap Value:

Scrap Steel Weight of Tower	336,000 #
	x <u>.10/ pound</u>
Scrap value of tower only	\$ 33,600.00
Scrap value of nacelle	<u>5,000.00</u>
Total value of turbine scrap	<u>\$ 38,600.00</u>
Scrap value of padmount	<u>\$ 5,000.00</u>
Sub-Total:	\$ 43,600.00
Net removal cost:	\$ 730.00

Decommissioning Plan for the Marble River Wind Farm

Anticipated life of turbines

Megawatt-scale wind turbine generators available on the market today have a life expectancy of more than 20 years. The tubular steel towers supporting the generators are of simple design and with basic routine maintenance will serve well beyond that of the generators.

As the generators approach the end of their expected life, technological advances should make available more efficient and cost effective generators that will economically drive the replacement of the existing generators.

Estimated costs of decommissioning

The cost of decommissioning the wind turbines is offset by the salvage value of the towers and turbine components.

Decommissioning costs per tower (in current dollars):

Removal of a Tower	
200 man hours x \$65/hour	\$13,000
Crane 5 days x \$2,900/day	\$14,500
Remove concrete to 36" below grade	
100 man hours x \$50/hour	\$5,000
Equipment 3 days x \$1,500/day	\$4,500
Remove access roads: (average of 1986 feet/turbine)	
100 man hours x \$65/hour	\$6,500
Equipment 6 days x \$1,500/day	\$9,000
Seeding and re-vegetation:	
80 man hours x \$30/hour	<u>\$2,400</u>
	\$54,900
Salvage value of a turbine: (based on Gamesa G90)	
Scrap value of tower steel (200 tons x \$200/ton)	\$40,000
Scrap value of generator components	<u>\$5,000</u>
	\$45,000
Estimated cost of decommissioning minus salvage value	<u>\$9,900</u>

Ensuring decommissioning and site restoration funds

The Applicant will continuously maintain a surety bond or equivalent financial security instrument payable to the Town for the removal of non-functioning turbines and appurtenant facilities, in a form and amount approved by the Town Board for the period of the life of the facility. Prior to the issuance of a building permit, The Applicant will, in writing, request approval of a proposed surety bond or financial security instrument in a proposed amount not less than \$200,000 for the removal of non-functioning turbines and associated facilities. The Applicant will fully fund the approved bond or financial instrument prior to issuance of a building permit for the Marble River Wind Farm. The Applicant recognizes that the Town may include a condition in any approval of the Project that prohibits transfer of the Project permits/approvals unless the Town

Board reasonably approves a decommissioning bond or financial security instrument for the prospective Transferee.

The costs associated with decommissioning and restoration will be studied by an independent licensed engineer retained by the town and paid by the applicant on a cycle beginning after the operations date of the wind farm and every five years thereafter for the life of the wind farm. A report of each study will be submitted to the Town Board. Any adjustment in the security value recommended by the engineer's report will be made within 60 days of delivery of the report to the Town Board.

Decommissioning process description

All decommissioning and restoration activities will adhere to the requirements of appropriate governing authorities and will be in accordance with all applicable federal, state, and local permits.

The decommissioning and restoration process comprises removal of above-ground structures, below-ground structures to a depth of 36 inches or greater, removal of access roads if required by the landowner, restoration of topsoil, re-vegetation and seeding, and a two year monitoring and remediation period.

Above-ground structures include the turbines, transformers, overhead collection lines, wind farm owned portions of the substation, maintenance buildings, and access gates. Below-ground structures include turbine foundations, collection system conduits, drainage structures, and access road sub-base material.

The process of removing structures involves evaluating and categorizing all components and materials into categories of recondition and reuse, salvage, recycling, and disposal. In the interest of increased efficiency and minimal transportation impacts, components and material may be stored on site in a pre-approved location until the bulk of similar components or materials are ready for transport. The components and material will be transported to the appropriate facilities for reconditioning, salvage, recycling, or disposal.

Turbine removal Access roads to turbines will be widened to sufficient width to accommodate movement of appropriate sized cranes or other machinery required for the disassembly and removal of the turbines. Control cabinets, electronic components, and internal cables will be removed. The blades, hub and nacelle will be lowered to grade for disassembly. The tower sections will be lowered to the ground where they will be further disassembled into transportable sections. The blades, hub, nacelle, and tower sections will either be transported whole for reconditioning and reuse or disassembled into salvageable, recyclable, or disposable components.

Turbine foundation removal. Topsoil will be removed from an area surrounding the foundation and stored for later replacement. Turbine foundations will be excavated to a depth sufficient to remove all anchor bolts, rebar, conduits, cable, and concrete to a depth of 36 inches below grade. The remaining excavation will be filled with clean sub-grade material of quality comparable to the immediate surrounding area. The sub-grade material will be compacted to a density similar to surrounding sub-grade material. All unexcavated areas compacted by equipment used in decommissioning shall be de-compacted in a manner to adequately restore the topsoil and sub-grade material to the proper density consistent and compatible with the surrounding area.

Underground collection cables The cables and conduits contain no materials known to be harmful to the environment and will be cut back to a depth greater than 36 inches. All cable and conduit buried greater than 36 inches will be left in place and abandoned.

WECS Decommissioning Process Description

Equipment Removal

1. **Turbine Removal** – Appropriate sized cranes will be mobilized and the hub with blades and nacelle will be removed to ground level for a scrap company to breakdown and strip high value components. The remaining material will be reduced to shippable dimensions and transported off site for proper disposal. The internal cabling will be removed and stored prior to delivery to a scrap company for recovery of high value copper conductor materials. The tower sections will be lowered to grade so they can be cut into transportable sections for delivery to a scrap iron purchaser. Control cabinets in the base will be stripped of high value components and the balance turned over to a scrap company for haul and disposal. The area will be thoroughly cleaned and all debris removed.
2. **Pad Mount Removal** – Cables will be disconnected from the transformer and high value reusable components will be recovered from the terminations. Cables between turbine base and transformer will be removed and stored prior to delivery to a scrap company for recovery of high value copper conductor materials. The pad mount will be removed from the base and placed on a truck which will deliver the unit to a specialty company for scrap out or refurbishment depending on market. The area will be thoroughly cleaned and all debris removed.¹
3. **Overhead Collection Lines** – Conductors will be removed and stored prior to delivery to a specialty scrap company for recycling. Switches and other hardware will be removed and delivered to a processing company for recycling of materials. Poles will be removed and holes filled with proper materials. Poles will be delivered to a facility for proper disposal. The area will be thoroughly cleaned and all debris removed.
4. **Substation** – For the equipment and area owned by the permittee, steel, conductors, buss work, switches, etc. will be removed and delivered to scrap company for disposal and recycling of materials as appropriate. Breakers and control panels will be stripped of high value components and balance turned over to scrap company for haul and disposal. The transformer will be removed from the base and placed on a truck which will deliver the unit to a specialty company for scrap out or refurbishment depending on market. The area will be thoroughly cleaned and all debris removed.

Foundation Removal

1. **Turbine Foundations** – Top soil will be removed to a proper storage pile to expose sub-grade materials, and that area will be excavated to expose the

turbine foundation pedestal. All anchor bolts, rebar, conduits, and concrete in the pedestal will be removed to 36" below grade. After removal of all noted foundation materials, the holes will be filled with clean compatible sub-grade material that is compacted to a density similar to the surrounding fields and then covered with the topsoil from the protected stockpile of material. All unexcavated areas compacted by equipment used in the decommissioning shall be tilled in a manner adequate to restore the topsoil and sub-grade material to the proper density – consistent with the surrounding fields. The area will be thoroughly cleaned and all debris removed.

2. Pad Mount Base - Top soil will be removed to a proper storage pile to expose sub-grade materials, and that area excavated to expose the pad mount foundation or pre-cast support vault. All anchor bolts, rebar, conduits, and concrete in the foundation or pre-cast support vault will be removed to 36" below grade. After removal of all noted foundation materials, the holes will be filled with clean compatible sub-grade material that is compacted to a density similar to the surrounding fields and then covered with the topsoil from the protected stockpile of material. All unexcavated areas compacted by equipment used in the decommissioning shall be tilled in a manner adequate to restore the topsoil and sub-grade material to the proper density – consistent with the surrounding fields. The area will be thoroughly cleaned and all debris removed.
3. Substation Area – For the area owned by the permittee, top soil will be removed to a proper storage pile to expose sub-grade materials, and the area excavated to expose the substation area foundations. All anchor bolts, rebar, conduits, and concrete in the foundations or pre-cast components will be removed to 36" below grade. After removal of all noted foundation materials, the holes will be filled with clean compatible sub-grade material that is compacted to a density similar to the surrounding fields and then covered with the topsoil from the protected stockpile of material. All unexcavated areas compacted by equipment used in the decommissioning shall be tilled in a manner adequate to restore the topsoil and sub-grade material to the proper density – consistent with the surrounding fields. The area will be thoroughly cleaned and all debris removed.

Underground Electrical Collection System

The underground electrical collection system will be designed and installed such that the main conductors will have a minimum of 36" of cover. The design includes the installation of a warning tape and tracer cable system to warn anyone who may be digging in the area both during plant operations and after decommissioning. The design is planned for

safety by getting sufficient cover to ensure that they will not be disturbed during normal agricultural operations.

Cables will be cut back in the area of the pad mounts to a minimum of 36" below grade and abandoned in place. The cables contain no materials known to be harmful to the environment.

Roadways/Rigging Pads

After completion of the decommissioning activities at each of the turbine sites, access road and rigging pad removal shall commence. Gravel will be removed from road and rigging pad surfaces to be transported from the site to an approved disposal location. The disposal location will be approved by the appropriate governing authority prior to the start of the decommissioning program. Geo-textile fabric (a tightly woven separation fabric placed during construction on the sub-grade under the gravel to keep the gravel from being pushed down into the sub-grade during wet periods) will be recovered and hauled offsite to an appropriate disposal site. All drainage structures including rip-rap, etc. will be removed and backfilled with clean, compatible sub-grade material. All road and other areas compacted during original construction or by equipment used in the decommissioning shall be tilled in a manner adequate to restore the sub-grade material to the proper density and depth consistent with the surrounding fields. Low areas will be filled with clean, compatible sub-grade material. After proper sub-grade depth is established, topsoil will be placed to a depth and density consistent with the surrounding field.

Access security gates will be maintained at all times until the road removal process is complete and the area is ready to be demobilized. The gate shall be removed and all materials recycled to the greatest extent possible. The ditch crossing will be removed if requested by the landowner and approved by the applicable highway authority. The area will be thoroughly cleaned and all debris removed.

All decommissioning activities shall be performed in accordance with all applicable federal, state, and local requirements in effect at the time of the plant decommissioning.

Security Instrument Proposal

Noble Environmental Power, LLC has carefully studied the decommissioning costs for this facility and has prepared a value curve for the value of the turbine components over time. Based on these estimates, we believe the cost risk of decommissioning is adequately secured by the fair market value of the turbines, if removed, through year eighteen when the cost of removal first exceeds the scrap value of the turbines. We are,

however, suggesting a more conservative approach to securing the removal of the turbines to provide the Town with the needed confidence in our approach.

Our proposal is to place a surety bond or equivalent financial security instrument on or before the commercial operations date for the facility in the amount of \$50,000 renewable on an annual basis. The security instrument shall include a provision that should another instrument of equal value fail to be placed prior to it's expiration it may be drawn without any other requirement. Bi-annually the values for turbine scrap and removal costs shall be audited and confirmed by an independent third party engineer in a report to the Town Board. Any adjustment in security value recommended by the engineer's report shall be in place within 60 days of the delivery of the report to the board.

Secondly, we further propose to place a larger replacement surety bond or equivalent financial security instrument on or before the fifteenth anniversary of the commercial operations date for the facility. (The year fifteen value of the turbines are still approximately double the estimated cost of removal.) The proposed value for the security would be ten thousand dollars per turbine (a total value which is roughly ten times the expected cost of decommissioning less the scrap value of the turbines as noted in the calculations included herein) or other value to be recommended by the independent engineer in his report the year before.

Revegetation and Reseeding

All Project areas not under cultivation or reserved for some other use by property owners will be revegetated or reseeded, as appropriate.

February 2006

WECS Removal Cost Analysis

Removal Costs (per tower):

Remove Tower

6 Men @ 4 days @ 8 hrs @ \$65 = \$ 12,480.00

Crane 5 days @ \$2500/day = 12,500.00

\$ 24,980.00

Remove Concrete to 3' Below Grade

4 men @ 24 hrs @ \$55 = 5,280.00

Trackhoe 3 days @ \$1600/day =	<u>4,800.00</u>
	\$ 10,080.00
Remove Roads (1,000' /Turbine)	
2 men @ 3 days @ 8 hrs @ 65 =	\$ 3,120.00
Grader & Loader 3 days @	
\$2,000 =	<u>6,000.00</u>
	\$ 9,120.00
Revegetation and reseedng	\$ 150.00
Sub-Total:	\$ 44,330.00

Scrap Value:

Scrap Steel Weight of Tower	336,000 #
	x <u>.10/ pound</u>
Scrap value of tower only	\$ 33,600.00
Scrap value of nacelle	<u>5,000.00</u>
Total value of turbine scrap	\$ <u>38,600.00</u>
Scrap value of padmount	\$ <u>5,000.00</u>
Sub-Total:	\$ 43,600.00
Net removal cost:	\$ 730.00

Introducing -

The *FREE* Center

Fenner Renewable Energy Education Center

Capital Campaign
2006

Introduction -

The Fenner Wind Farm is located in Madison County, New York, ten minutes south of the New York State Thruway between Syracuse and Utica. It is already a destination for local scout troops, public school groups, college classes, professional organizations, U.S. Senators and government fact finding groups, and thousands of casual visitors each year. All these visitors come, yet there is no focal point to which they can arrive. Instead, the interested parties find themselves stopping by the side of the road, asking local residents about the wind farm, or setting up an ad hoc tour with a local volunteer. The proposed Fenner Renewable Energy Education (FREE) Center will provide just such a focal point as well as an opportunity to further benefit the community.

Read What Fenner-Area Neighbors Say:

We're proud of our windmills & what they do to preserve our farmland community & our environment. The birds & wildlife thrive, the small farms can sustain themselves & our beautiful rural community will not only survive, but contribute to the clean energy that is our future.

— Laura Costello

The Fenner Renewable Energy Education Center is a necessary vehicle to educating the public. The FREE Center will educate all generations about wind power and other renewable energy sources.

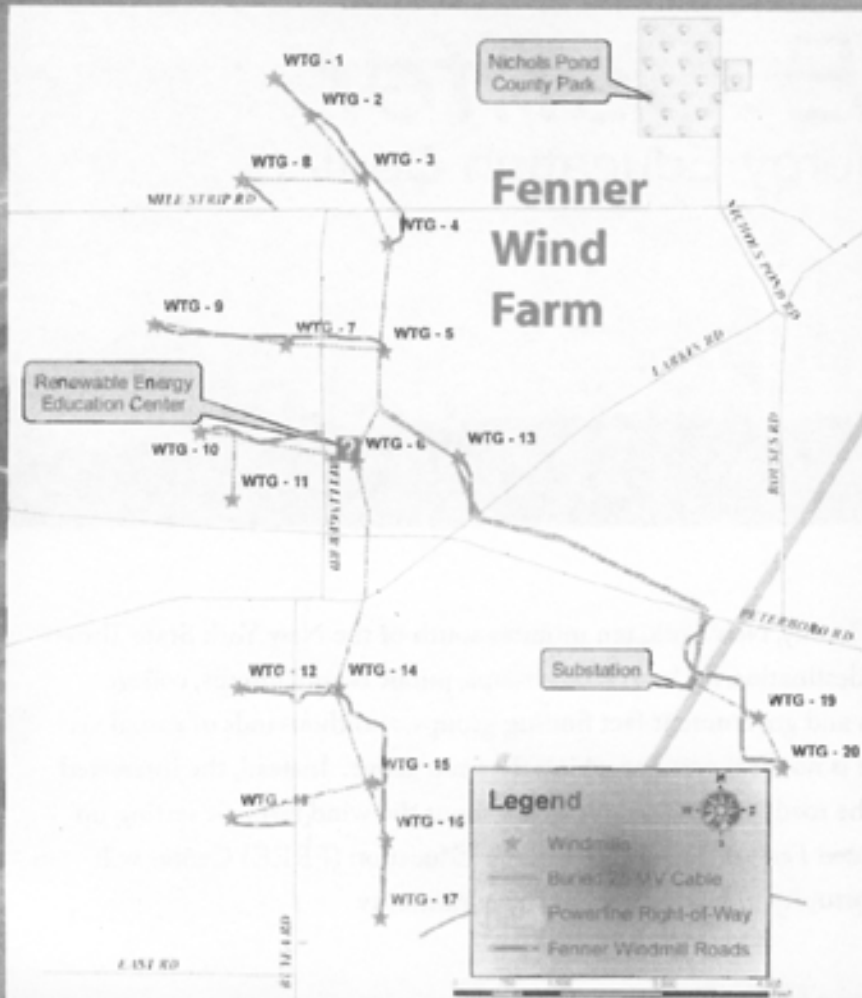

— Sue Snyder

We have an incredible opportunity to give our children a future that is not dependent on foreign fuel; a future that could have cleaner air than we have today. A future to appreciate renewable resources. A future they can give to their children. That future is wind power.

— Anne Jones

A First for the Northeastern

- × A renewable energy center located in the middle of an operating wind farm. Operating wind turbines surround the site in all directions.
- × Located a short ten-minute drive from New York State Thruway exit 34. The wind farm is visible from the Thruway.
- × In addition to Fenner, the Madison wind farm is viewable from the Center site. Also, two Nine Mile II nuclear plant cooling towers are visible to the North a short distance down the road demonstrating contrast.
- × Will feature bus parking for large groups, interpretive center, walking trails, turbine blade and picnic pavillion.
- × Center will highlight all forms of renewable energy including wind, solar, hydro and fuel cells, ethanol, animal draft power, etc.
- × Turbine output directly linked to center so participants can see level of electricity production in real time.

A Beacon for a Better Energy Future

United States

Fenner Renewable Energy Education Center

Located in the heart of the Northeast in Upstate New York, a day trip from major metropolitan centers:

- New York City - 4.5 hours
- Boston - 5.0 hours
- Montreal - 5.0 hours
- Philadelphia - 4.5 hours
- Burlington - 5.0 hours
- Albany - 2.5 hours
- Buffalo - 3.0 hours
- Syracuse - 0.5 hours

The Fenner Renewable Energy Education (FREE) Center is currently seeking funding for two phases of design and construction. Phase I will be a low impact parking area and interpretive center with kiosks and a self guided driving tour. Phase II will be a LEED certified green building incorporating the newest advances in low-impact, high efficiency design to provide a meeting and educational space, a covered picnic area, a display of real-time data on the wind farm operation, and a interface with the wind farm operators.

Phase I Goals

- Informational and interpretive kiosks along a walking trail;
- Low-maintenance landscaping using native plants;
- A paved parking area suitable for 1 to 2 buses and 10 autos;
- A picnicking area;
- A turbine blade on display (donated by General Electric);
- Self-guided auto tour; and
- Restrooms featuring composting toilets.

Phase II Goals

- An energy efficient, green building with an open floor plan able to accommodate organized groups and large meetings.
- Information and interpretive displays at and in the building, including information on wind energy and other renewable technologies (biomass, solar, fuel cells, hydro, ethanol, animal draft power, etc.).
- Real-time computer link displaying operational parameters of the wind generators.

CHAPTER I. PROJECT OVERVIEW

THE CLAIM AGAINST WIND DEVELOPMENT

Wind energy is the fastest growing domestic energy resource. Between 1998 and 2002 installed capacity grew from 1848 MW to 4685 MW, a compound growth rate of 26 percent. Since wind energy is now broadly competitive with many traditional generation resources, there is wide expectation that the growth rate of the past five years will continue. (Source for statistics: www.nwea.org).

As the pace of wind project development has increased, opponents have raised claims in the media and at siting hearings that wind development will lower the value of property within view of the turbines. This is a serious charge that deserves to be seriously examined.

NO EXISTING EMPIRICAL SUPPORT

As a result of the expansion of capacity from 1998 to 2002, it is reasonable to expect any negative effect would be revealed in an analysis of how already existing projects have affected property values. A search for either European or United States studies on the effect of wind development on property values revealed that no systematic review has as yet been undertaken.

As noted above, the pace of development and siting hearings is likely to continue, which makes it important to do systematic research in order to establish whether there is any basis for the claims about harm to property values. (For recent press accounts of opposition claims see: *The Charleston Gazette*, WV, March 30, 2003; and *Copley News Service*, Ottawa, IL, April 11, 2003).

This REPP Analytical Report reviews data on property sales in the vicinity of wind projects and uses statistical analysis to determine whether and the extent to which the presence of a wind power project has had an influence on the prices at which properties have been sold. The hypothesis underlying this analysis is that if wind development can reasonably be claimed to hurt property values, then a careful review of the sales data should show a negative effect on property values within the viewshed of the projects.

A SERIOUS CHARGE SERIOUSLY EXAMINED

The first step in this analysis required assembling a database covering every wind development that came on-line after 1998 with 10 MW installed capacity or greater. (Note: For this Report we cut off projects that came on-line after 2001 because they would have insufficient data at this time to allow a reasonable analysis. These projects can be added in future Reports, however.) For the purposes of this analysis, the wind developments were considered to have a visual impact for the area within five miles of the turbines. The five mile threshold was selected because review of the literature and field experience suggests that although wind turbines may be visible beyond five miles, beyond this distance, they do not tend to be highly noticeable, and they have relatively little influence on the landscape's overall character and quality. For a time period covering roughly six years and straddling the on-line date of the projects, we gathered the records for all property sales for the view shed and for a community comparable to the view shed.

For all projects for which we could find sufficient data, we then conducted a statistical analysis to determine how property values changed over time in the view shed and in the comparable community. This database contained more than 25,000 records of property sales within the view shed and the selected comparable communities.

THREE CASE EXAMINATIONS

REPP looked at price changes for each of the ten projects in three ways: Case 1 looked at the changes in the view shed and comparable community for the entire period of the study; Case 2 looked at how property values changed in the view shed before and after the project came on-line; and Case 3 looked at how property values changed in the view shed and comparable community after the project came on-line.

Case 1 looked first at how prices changed over the entire period of study for the view shed and comparable region. Where possible, we tried to collect data for three years preceding and three years following the on-line date of the project. For the ten projects analyzed, property values increased faster in the view shed at eight of the ten projects. In the two projects where the view shed values increased slower than for the comparable community, special circumstances make the results questionable. Kern County, California is a site that has had wind development since 1981. Because of the existence of the old wind machines, the site does not provide a look at how the new wind turbines will affect property values. For Fayette County, Pennsylvania the statistical explanation was very poor. For the view shed the statistical analysis could explain only 2 percent of the total change in prices.

Case 2 compared how prices changed in the view shed before and after the projects came on-line. For the ten projects analyzed, in nine of the ten cases the property values increased faster after the project came on-line than they did before. The only project to have slower property value growth after the on-line date was Kewaunee County, Wisconsin. Since Case 2 looks only at the view shed, it is possible that external factors drive up prices faster after the on-line date and that analysis is therefore picking up a factor other than the wind development.

Finally, **Case 3** looked at how prices changed for both the view shed and the comparable region, but only for the period after the projects came on-line. Once again, for nine of the ten projects analyzed, the property values increased faster in the view shed than they did for the comparable community. The only project to see faster property value increases in the comparable community was Kern County, California. The same caution applied in Case 1 is necessary in interpreting these results.

If property values had been harmed by being within the view-shed of major wind developments, then we expected that to be shown in a majority of the projects analyzed. Instead, to the contrary, we found that for the great majority of projects the property values actually rose more quickly in the view shed than they did in the comparable community. Moreover, values increased faster in the view shed after the projects came on-line than they did before. Finally, after projects came on-line, values increased faster in the view shed than they did in the comparable community. In all, we analyzed ten projects in three cases; we looked at thirty individual analyses and found that in twenty-six of those, property values in the affected view shed performed better than the alternative.

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

This study is an empirical review of the changes in property values over time and does not attempt to present a model to explain all the influences on property values. The analysis we conducted was done solely to determine whether the existing data could be interpreted as supporting the claim that wind development harms property values. It would be desirable in future studies to expand the variables incorporated into the analysis and to refine the view shed in order to look at the relationship between property values and the precise distance from development. However, the limitations imposed by gathering data for a consistent analysis of all major developments done post-1998 made those refinements impossible for this study. The statistical analysis of all property sales in the view shed and the comparable community done for this Report provides no evidence that wind development has harmed property values within the view shed. The results from one of the three Cases analyzed are summarized in Table 1 and Figure 1 below.

REGRESSION ANALYSIS

REPP used standard simple statistical regression analyses to determine how property values changed over time in the view shed and the comparable community. In very general terms, a regression analysis "fits" a linear relationship, a line, to the available database. The calculated line will have a slope, which in our analysis is the monthly change in average price for the area and time period studied. Once we gathered the data and conducted the regression analysis, we compared the slope of the line for the view shed with the slope of the line for the comparable community (or for the view shed before and after the wind project came on-line).

TABLE 1: SUMMARY OF STATISTICAL MODEL RESULTS FOR CASE 1

Project/On-Line Date	Monthly Average Price Change (\$/month)	
	View Shed	Comparable
Riverside County, CA	\$1,719.66	\$814.17
Madison County, NY (Madison)	\$576.22	\$245.51
Carson County, TX	\$820.47	\$296.54
Kewaunee County, WI	\$434.48	\$116.18
Searsburg, VT	\$536.41	\$330.61
Madison County, NY (Fernalt)	\$368.47	\$245.51
Somerset County, PA	\$190.07	\$100.06
Buena Vista County, IA	\$407.86	\$341.87
Kern County, CA	\$492.38	\$684.16
Fayette County, PA	\$115.96	\$479.20

While regression analysis gives the best fit for the data available, it is also important to consider how "good" (in a statistical sense) the fit of the line to the data is. The regression will predict values that can be compared to the actual or observed values. One way to measure how well the regression line fits the data calculates what percentage of the actual variation is explained by the predicted values. A high percentage number, over 70%, is generally a good fit. A low number, below 20%, means that very little of the actual variation is explained by the analysis. Because this initial study had to rely on a database constructed after the fact, lack of data points and high variation in the data that was gathered meant that the statistical fit was poor for several of the projects analyzed. If the calculated linear relationship does not give a good fit, then the results have to be looked at cautiously.

FIGURE 1: MONTHLY PRICE CHANGE IN THE VIEW SHED
RELATIVE TO COMPARABLE: ALL YEARS

CASE RESULT DETAILS

Although there is some variation in the three Cases studied, the results point to the same conclusion: the statistical evidence does not support a contention that property values within the view shed of wind developments suffer or perform poorer than in a comparable region. For the great majority of projects in all three of the Cases studied, the property values in the view shed actually go up faster than values in the comparable region. Analytical results for all three cases are summarized in Table 2 below.

TABLE 2: DETAILED STATISTICAL MODEL RESULTS

Location: Buena Vista County, IA
Project: Storm Lake I & II

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data Comparable, all data	Jan 96 - Oct 02 Jan 96 - Oct 02	\$401.86 \$341.87	0.67 0.72	The rate of change in average view shed sales price is 16% greater than the rate of change of the comparable over the study period.
Case 2	View shed, before View shed, after	Jan 96 - Apr 99 May 99 - Oct 02	\$370.52 \$631.12	0.51 0.53	The rate of change in average view shed sales price is 70% greater after the on-line date than the rate of change before the on-line date.
Case 3	View shed, after Comparable, after	May 99 - Oct 02 May 99 - Oct 02	\$631.12 \$234.84	0.53 0.23	The rate of change in average view shed sales price after the on-line date is 2.7 times greater than the rate of change of the comparable after the on-line date.

The EROCLIDE WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

Case 1	View shed, all data	Jan 97 - Jan 03	\$388.47	0.35	The rate of change in average view shed sales price is 50% greater than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 97 - Jan 03	\$245.51	0.34	
Case 2	View shed, before	Jan 97 - Nov 01	-\$587.95	0.50	The rate of decrease in average view shed sales price after the on-line date is 29% lower than the rate of sales price increase before the on-line date.
	View shed, after	Dec 01 - Jan 03	-\$418.98	0.04	
Case 3	View shed, after	Dec 01 - Jan 03	-\$418.98	0.04	The rate of decrease in average view shed sales price after the on-line date is 37% less than the rate of decrease of the comparable after the on-line date.
	Comparable, after	Dec 01 - Jan 03	-\$663.38	0.03	

The Effect of Wind Development on Local Property Values

Location: **Riverside County, CA**

Project: **Cabazon, Enron, Energy Unlimited, Mountain View Power Partners I & II, Westwind**

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 96 - Nov 02	\$1,719.65	0.92	The rate of change in average view shed sales price is 2.1 times greater than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 96 - Nov 02	\$814.17	0.81	
Case 2	View shed, before	Jan 96 - Apr 99	\$1,062.83	0.68	The rate of change in average view shed sales price is 86% greater after the on-line date than the rate of change before the on-line date.
	View shed, after	May 99 - Nov 02	\$1,978.88	0.81	
Case 3	View shed, after	May 99 - Nov 02	\$1,978.88	0.61	The rate of change in average view shed sales price after the on-line date is 63% greater than the rate of change of the comparable after the on-line date.
	Comparable, after	May 99 - Nov 02	\$1,212.14	0.74	

Location: **Bennington and Windham Counties, VT**

Project: **Searsburg**

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 94 - Oct 02	\$536.41	0.70	The rate of change in average view shed sales price is 62% greater than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 94 - Oct 02	\$330.81	0.45	
Case 2	View shed, before	Jan 94 - Jan 97	-\$301.52	0.68	The rate of change in average view shed sales price after the on-line date increased at 2.6 times the rate of decrease before the on-line date.
	View shed, after	Feb 97 - Oct 02	\$771.06	0.71	
Case 3	View shed, after	Feb 97 - Oct 02	\$771.06	0.71	The rate of change in average view shed sales price after the on-line date is 18% greater than the rate of change of the comparable after the on-line date.
	Comparable, after	Feb 97 - Oct 02	\$655.20	0.78	

Location: **Somerset County, PA**

Project: **Excelon, Green Mountain**

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 97 - Oct 02	\$190.07	0.30	The rate of change in average view shed sales price is 90% greater than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 97 - Oct 02	\$100.06	0.07	
Case 2	View shed, before	Jan 97 - Apr 00	\$277.99	0.37	The rate of change in average view shed sales price after the on-line date is 3.5 times greater than the rate of change before the on-line date.
	View shed, after	May 00 - Oct 02	\$960.59	0.52	
Case 3	View shed, after	May 00 - Oct 02	\$960.59	0.62	The rate of change in average view shed sales price after the on-line date increased at 2.3 times the rate of decrease in the comparable after the on-line date.
	Comparable, after	May 00 - Oct 02	-\$418.73	0.23	

Each of the three Cases takes a different approach to evaluating the price changes in the view shed and comparable community. By finding consistent results in all three Cases, the different approaches help to address concerns that could be raised about individual approaches. The selection of the comparable community is based upon a combination of demographic statistics and the impressions of local assessors and is inherently subjective. It is possible that arguments about the legitimacy of the selection of the comparable could arise and be used to question the legitimacy of the basic conclusion. However, since Case 2 looks only at the view shed and since the results of the Case 2 analysis are completely consistent with the other Cases, the selection of the comparable community will not be crucial to the legitimacy of the overall conclusion. To take another example, Case 1 uses data from the entire time period, both before and after the on-line date. We anticipate possible criticisms of this Case as masking the "pure" effect of the development that would only occur after the project came on-line. However, Cases 2 and 3 look separately at the before and after time periods and produce results basically identical to the Case 1 results. Because all three Cases produce similar results, Cases 2 and 3 answer the concerns about Case 1.

THE DATABASE

The results of the analysis depend greatly upon the quality of the database that supports the analysis. The Report is based on a detailed empirical investigation into the effects of wind development on property values. The study first identified the 27 wind projects over 10 MW installed capacity that have come on-line since 1998. REPP chose the 1998 on-line date as a selection criterion for the database because it represented projects that used the new generation of wind machines that are both taller and quieter than earlier generations. (REPP did not consider projects that came on-line in 2002 or after since there would be too little data on property values after the on-line date to support an analysis. These projects can be added to the overall database and used for subsequent updates of this analysis, however.) REPP chose the 10 MW installed capacity as the other criterion because if the presence of wind turbines is having a negative affect it should be more pronounced in projects with a large rather than small number of installations. In addition, we used the 10 MW cut-off to assure that the sample of projects did not include an over-weighting of projects using a small number of turbines.

Of the 27 projects that came on-line in 1998 or after and that were 10MW or larger installed capacity, for a variety of reasons, 17 had insufficient data to pursue any statistical analysis. For six of the 17 projects we acquired the data, but determined that there were too few sales to support a statistical analysis. For two of the remaining 11, state law prohibited release of property sales information. The remaining nine projects had a combination of factors such as low sales, no electronic data, and paper data available only in the office. (For a project-by-project explanation, see Chapter 2 of the Report.)

For each of the remaining 103 projects, we assembled a database covering roughly a six-year period from 1996 to the present. For each of these projects we obtained individual records of all property sales in the "view shed" of the development for this six-year period. We also constructed a similar database for a "comparable community" that is a reasonably close community with similar demographic characteristics. For each of the projects, we selected the comparable community on the basis of the demographics of the community and after discussing the appropriateness of the community with local property assessors. As shown in Table 3 below, the database of view shed and comparable sales included more than 25,000 individual property sales. The initial included database of view shed and comparable sales included over 25,000 individual property sales. After review and culling, the final data set includes over 24,500 individual property sales, as shown in Table 3 below.

TABLE 4: NUMBER OF PROPERTY SALES ANALYZED, BY PROJECT

Project/On-Line Date	Viewshed Sales	Comparable Sales	Total Sales
Searsburg, VT / 1997	2,788	562	3,340
Kern County, CA / 1999	745	2,122	2,867
Riverside County, CA / 1999	5,513	3,592	9,105
Buena Vista County, IA / 1999	1,557	1,656	3,213
Howard County, TX / 1999*	2,192	n/a	2,192
Kewaunee County, WI / 1999	320	295	624
Madison Co./Madison, NY / 2000	219	591	810
Madison Co./Fenner, NY / 2000**	453	591	1,044
Somerset County, PA / 2000	902	422	1,384
Fayette County, PA / 2001	39	50	89
Carson County, TX / 2001	45	224	269
TOTAL	14,842	9,504	24,346

*Howard County, TX comparable data not received at time of publication

**Both wind projects in Madison County, NY, are the same as comparable. Column totals adjusted to eliminate double counting.

RECOMMENDATIONS

The results of this analysis of property sales in the vicinity of the post-1998 projects suggest that there is no support for the claim that wind development will harm property values. The data represents the experience up to a point in time. The database will change as new projects come on-line and as more data becomes available for the sites already analyzed. In order to make the results obtained from this initial analysis as useful as possible to siting authorities and others interested in and involved with wind development, it will be important to maintain and update this database and to add newer projects as they come on-line.

Gathering data on property sales after the fact is difficult at best. We recommend that the database and analysis be maintained, expanded and updated on a regular basis. This would entail regularly updating property sales for the projects already analyzed and adding new projects when they cross a predetermined threshold, for example financial closing. In this way the results and conclusions of this analysis can be regularly and quickly updated.

CHAPTER II. METHODOLOGY

The work required to produce this report falls into two broad categories -- data collection and statistical analysis. Each of these areas in turn required attention to several issues that determine the quality of the result.

According to the American Wind Energy Association (AWEA), approximately 225 wind projects were completed or under development in the United States as of 2002. The first wave of major wind project development in the United States took place between approximately 1981 and 1995. Wind farm development slowed considerably in 1996, with only three wind projects installed, the largest of which was 600 kW. The first major post-1996 project was the 6 MW Searsburg site in Bennington County, Vermont, which came on-line in 1997.

A. PROJECT SELECTION CRITERIA

This report focuses on major wind farm projects that constitute the second wave of wind farm development. This second wave of projects employs modern wind turbine technology likely to be installed over the next several years as part of continuing U.S. wind farm development. Compared to the previous generation of wind turbines, modern wind turbines generally have greater installed capacities, taller towers, larger turbine blades, lower rotational speeds and reduced gearbox noise.

In addition to the 6 MW Searsburg wind farm, this report analyzes potential property value effects for wind farms of 10 MW capacity or greater installed from 1998 through 2001. Projects completed in 2002 and later are excluded from this analysis because not enough time has elapsed to collect sufficient data to statistically determine post-installation property value effects. To determine property value trends prior to wind farm installation, we collected property sales data from three years prior to the on-line year to the present for each of the wind farms analyzed.

Twenty-seven wind farm projects met the project selection criteria.

B. DATA COMPILATION

Once the projects were selected for analysis, the process of acquiring data was initiated through phone calls to county assessment offices. For each project, varying sources of data and information were available, ranging from websites with on-line data, purchased data on CD-ROM or via e-mail from government offices, purchased data from private vendors or postal carried paper records. In many cases data was only available in paper, but not by mail -- a person would physically have to appear before the assessment office clerk and search storage boxes, which in some cases had been archived to remote locations for long-term storage. Many states do not require local offices to retain records past certain age limits, often between one to five years. After that, files may be destroyed, and in some cases had been.

Where paper records were obtained, data was transferred into electronic form through scanning or manual data entry. In many cases, both with paper and/or electronic data, the fields we received did not provide good geographic specificity. For example, in some cases, townships and/or cities, but not street addresses were identified. Where street addresses were included, in some cases not all properties had street addresses given, or street addresses were truncated or otherwise incomplete.

Out of the 27 counties with wind farms meeting the project selection criteria, ten sites were selected for statistical analysis based on availability of property sales data. The other 17 eligible sites were excluded from statistical analysis for a number of reasons, including insufficient sales to perform statistical analysis (for example, one site had only five sales in five years), lack of readily available data (data requiring in-person visits to the Assessor's Office to manually go through paper files), and two cases where state law prohibited the Assessor's Office from releasing property sales data to the public.

This report contains one section for each of the ten sites analyzed, with project site and community descriptions, view shed and comparable selection details, and analytical results and discussion. In addition, the report contains one section providing detailed explanations of why each of the 17 other sites are excluded from analysis. The dataset used in this report, exclusive of proprietary data, is available on the REPP web site at www.repp.org, or by request from REPP.

C. VIEW SHED DEFINITION

In order to determine whether the presence of a wind farm has an adverse effect on property values in the wind farm's vicinity, the area potentially affected by the wind farm must be defined. In this report, the area in which potential property value effects are being tested for is termed the "view shed."

How the view shed is defined will affect the type of data required to test for property value effects, as well as the analytical model employed. Choosing the value of the appropriate radius for such a view shed is subjective. To help determine the radius, numerous studies regarding line-of-sight impacts were reviewed, and interviews with a power industry expert on visual impacts of transmission lines were conducted. In the end, three separate resources for estimates of visual impact were used to support defining the view shed as the area within a five-mile radius of the wind farms. These resources are:

- o The U.S. Department of Agriculture (USDA). In a handbook titled "National Forest Landscape Management" (1973) developed for the Forest Service by the USDA, three primary zones of visual impact are defined: foreground, middleground and background. These zones relate to the distance from an object in question, be it a fire lookout tower, tall tree, or mountain in the distance. In this definition, foreground is 0 to 1/2 mile, middleground is 1/4 to 5 miles and background is 3 to 5 miles. The USDA handbook states that for foreground objects people can discern specific sensory experiences such as sound, smell and touch, but for background objects little texture or detail are apparent, and objects are viewed mostly as patterns of light and dark.
- o The Sinclair-Thomas Matrix. This is a subjective study of the visual impact of wind farms published in the report *Wind Power in Wales, UK* (1999). Visual impact is defined in a matrix of distance from a wind turbine versus tower hub height. At the highest hub height considered in the matrix, 95 meters (312 feet), the visual impact of wind towers is estimated to be moderate at a distance of 12 km (7.5 miles). The matrix estimates that not until a distance of 40 km (25 miles) is there "negligible or no" visual impact from wind turbines under any atmospheric condition. Of the ten sites considered in this REPP report, the majority of towers have hub heights of 60 to 70 meters, which, according to the Sinclair-Thomas matrix, corresponds to moderate visual impact at a distance of 9 to 10 km (5.6– 6.2 miles).

- o **Interviews with Industry Experts.** A power industry analyst with extensive experience in quantitative analysis of visual impacts of transmission lines stated in an interview that a rule of thumb used for the zone of visual influence of installations such as transmission lines and large wind turbines is a distance of approximately five miles.

There are other possible definitions of the view shed. At present, new proposals are sometimes required to conduct a Zone of Visual Influence (ZVI) analysis to determine the extent of visibility of a development. The zone comprises a visual envelope within which it is possible to view the development, notwithstanding the presence of any intervening obstacles such as forests, buildings, and other objects. Digital terrain computer programs are used to calculate and plot the areas from which the wind farm can be seen on a reference grid that indicates how many turbines can be seen from a given point. One weakness of the standard ZVI analysis is that all turbines are given equal weight of visual impact. That is, a turbine 20 miles from the viewer is assigned the same visual impact as a turbine one mile away.

Possible definitions for view sheds include the set of real properties that have a view of one or more wind turbines from inside the residence, that have a view of one or more turbines from any point on the property, or that are simply within some defined distance from the wind turbines, whether there is a view from each property in that area or not. In the last case, it is assumed that property owners in the area will still be potentially affected by views of the wind farms, as they will see them while traveling and conducting business in their vicinity.

Because this project lacked the resources to determine (through site visits, interviews, or other means) whether or not individual properties in the vicinity of the ten selected wind farms have a direct view of the wind turbines, the view shed is defined as all properties within a given radius of the outermost wind turbines in a wind farm. The value of this radius will clearly affect the results of the analysis. If the radius is too large, including many properties not potentially affected will overshadow the potential effect of the presence of wind turbines on property values. If the radius is too small, not all potentially effected properties will be accounted for in the analysis, and the number of data points gathered may be too small to yield valid statistical results.

D. COMPARABLE CRITERIA

With the view shed of the wind farm defined, a set of neighboring communities outside of the view shed is selected to evaluate trends in residential house sales prices without the potential effects of wind farms on property values. These townships and incorporated cities are required to be clearly outside of the view shed area and not containing any large wind turbines. This selection is the "comparable" region. To define the comparable REPP consulted with local County Assessors and analyzed 1990 and 2000 U.S. Census data for the townships and incorporated cities under consideration.

Criteria used in selection of comparable communities include economic, demographic, and geographic attributes and trends. The goal in selecting comparable communities is to have communities that are as similar as possible with respect to variables that might affect residential house values, with the exception of the presence or absence of wind farms. When possible, comparable communities are selected in the same county as the wind farm locations. If this is not possible due to placement of wind farm or availability of suitable data, comparable communities are selected from counties immediately adjacent to the county containing the wind farm.

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

After considering a number of criteria, including population, income level, poverty level, educational attainment, number of homes, owner occupancy rate, occupants per household, and housing value, five criteria from 1990 and 2000 U.S. Census were selected for evaluation:

- ∞ Population
- ∞ Median Household Income
- ∞ Ratio of Income to Poverty Level
- ∞ Number of Housing Units
- ∞ Median Value of Owner-occupied Housing Units

Data for these criteria is obtained for both the wind farm and comparable communities. Percent change from 1990 to 2000 for each criterion is calculated for each township or city considered as potentially comparable areas. The criteria are used in the following manner:

- a) Change in population is calculated to identify any communities that had excessively large changes in population relative to the change in population from 1990 to 2000 in the wind farm area. Such large changes could indicate either a major construction boom, or major exodus of habitants from an area, which could skew comparisons in residential home values over the period in question. These communities are eliminated as possible comparables.
- b) The average median household income in the wind farm communities in 1990 and 2000 is calculated. The first criterion is that comparable communities should have similar median household incomes in 2000. The second criterion is that median incomes should not have changed at significantly different rates from 1990 to 2000 between wind farm and comparable communities. Communities that meet both criteria are considered as potential comparables.
- c) The percent of the population whose income is below poverty level is calculated from the ratio of income to poverty level. Absolute poverty levels and percent changes in poverty levels from 1990 to 2000 are compared. Communities that have significantly different poverty levels or rates of change of these levels as compared to the wind farm areas are eliminated as possible comparables.
- d) Change in the number of housing units is used to identify any communities that had excessively large changes in housing relative to the change in housing from 1990 to 2000 in the wind farm area. Such large changes could indicate a major construction boom, or reduction in housing stock, which could skew comparisons in residential home values over the period in question. These communities are eliminated as possible comparables.
- e) The average median house value in the wind farm communities in 1990 and 2000 is obtained from Census data. These values are owner-reported, and therefore may not accurately reflect actual market value of the properties. The criterion is that comparable communities should have similar median house values. Communities meeting these criteria are considered as potential comparables.

Communities that meet all five of the above criteria are selected for consideration as comparable communities. In addition to analysis of Census data, interviews with County Assessors, other local and state officials, and in some cases with knowledgeable real estate agents are taken into account in the selection of comparables.

E. ANALYSIS

i. Literature Review

In selecting the type of analysis to use in determining whether there is any statistical evidence that wind farms negatively affect property values, we first conducted literature research to identify any studies previously conducted for this purpose. We found only four studies relating wind and property value effects, three of which are only qualitative.

A 1996 quantitative study, *Social Assessment of Wind Power* (Institute of Local Government Studies, Denmark), applied regression analysis to determine the effect of individual wind turbines, small wind turbine clusters, and larger wind parks on residential property values. The regression used the hedonic method, discussed in more detail below, in which site-specific data on a number of quantitative and qualitative variables is used to predict housing values. The study concluded that homes close to a wind turbine or turbines ranged in value from DKK 16,200 to 24,000 (approximately \$2,200 to \$3,600) less than homes further away. The study had a number of weaknesses, including a lack of definition of the distance from turbines, lack of specification of the size and number of turbines, and regression on a very small data sample. In contrast, a 2002 qualitative study, *Public Attitudes Towards Wind Power* (Danish Wind Industry Association), quoted the 1997 *Sydhjy Study* as concluding that residents closer than 500 meters to the nearest wind turbine tend to be more positive about wind turbines than residents further away.

A 2001 qualitative study, *Social Economics and Tourism* (Siachir Knight Merril), said that for highly sought after properties along Salmon Beach, Australia closer than 200 meters from wind turbines, the general consensus among local real estate agents is that "property prices next to generators have stayed the same or increased after installation." However, the study concluded that while properties with wind turbines on them may increase in value, other properties may be adversely affected if within sight or audible distance of the wind turbines. Finally, the 2002 qualitative study, *Economic Impacts of Wind Power in Kittitas County* (ECCO Northwest), concluded from interviews with assessors around the United States that there is no evidence of a negative impact on property values from wind farms. The weakness of the study is that it relies on subjective comment to arrive at its conclusion.

We also reviewed several studies that attempt to quantify the visual and property value impacts of electric transmission towers and lines. There is a large body of information on this subject, as transmission lines have been the subject of scrutiny and regulation for many years.

A 1993 study, *The Effects of Overhead Transmission Lines on Property Values* (C.A. Kroll and T. Priestley), reviews the methodology and conclusions of a number of studies on overhead transmission lines and property values over the 15 year period of 1977 through 1992. This study was very helpful in identifying the types of analysis, and their strengths and weaknesses, which could be adopted for use in this REPP report. The study concluded that appraisal offices have the longest history of studying and evaluating line impacts, but lack in-depth statistical analysis to verify obtained results. Data obtained from face-to-face conversation and through surveys attempts to ascertain the attitudes and reactions of property owners to transmission equipment, but personal opinions were found to produce widely varying results. Statistical analysis of appraiser findings provided a better interpretation of appraiser information, but produced varying results due to different methodologies.

ii. Choice of Analytic Method

A number of analytic methods may be used to assess property value impacts from wind farms, ranging from interviews with assessors and surveys of residents to simple regression models and hedonic regression analysis. In order to produce results that could determine whether or not there was statistical evidence that wind farms have a negative impact on property values, simple linear regression analysis on property sales price as a function of time was selected.

A more complex method, hedonic regression analysis, can also be used to gauge property value impacts. Hedonic analysis, used in a number of studies on visual impacts of transmission lines, employs both quantitative and qualitative values to describe the property and local, regional, and even national parameters that may influence housing values. Property data such as number of bedrooms and bathrooms, linoleum or tile floors, modern appliances, kitchen cabinets or not are collected for each property in the study area, as well community information such as school district quality, subjective criteria derived from interviews with every resident in a study area, and other parameters. However, because this report is based on historic data, much of the detail needed for a hedonic analysis may not be available. An important consideration for this analysis, given the limits of the data, was to apply a consistent methodology to the site analyses. The only data consistent across all sites is sales date and sales price.

iii. Data Analysis

The key variables used in this analysis are sale price, sale date, and one locational attribute allowing data to be separated into view shed and comparable data sets. The first step of analysis was to remove any erroneous data from the dataset. Sales with incomplete information, duplicate sales, and zero price were removed. Parcel sales under \$1,000 were also removed, as they often represent transfer within a family or business, rather than a bona fide sale. Finally, any sales with values much higher than any other sales were researched to determine whether or not that sale was bona fide. Interviews with assessors with knowledge of the properties in question were used to determine whether these high value sales were erroneous. Where they were, they were removed.

The second step in data analysis was to reduce cyclic effects of the real estate market on sales prices, as well as to reduce the high variability and heterogeneity of the data when viewed on a day sale basis. First, for each month, we calculated the monthly average sales price for each month to eliminate the variability of day-to-day sales. In some cases data supplied was already in monthly averaged form. Second, a six-month trailing average of the average monthly sales price is used to smooth out seasonal fluctuations in the real estate market. The averaging technique used the current month sales plus the previous six months of sales to compute trailing averages.

Third, a unit of analysis is defined. Because this project generally lacks resources to identify properties by street address, the smallest units of geographical analysis used are townships and incorporated cities within each county. Townships that are partly but not fully within the view shed radius are excluded from the view shed. In some cases zip code 4-digit ZIP+4 regions are used to identify location, and in some cases where the data offered an other alternative, individual street locations were manually identified in order to define the location of properties within the view shed and comparable.

Fourth, as stated above, linear regression is selected as the method to test for potential property value impacts. A least-squares linear regression of the six-month trailing average price is constructed for the view shed and comparable areas to determine the magnitude and rate of change in property sales price for each of the areas. The regression yields an equation for the line that best fits the data. The slope of this line gives the month-by-month expected change in the price of homes in the view shed and comparable areas. The regression also yields a value for "R2."

The R2 value measures the goodness of fit of the linear relationship to the data, and equals the percentage of the variance (change over time) in the data that is described by the regression model. The value of R2 ranges from zero to one. If R2 is small, say less than 0.2 or 0.3, the model explains only 20 to 30 percent of the variance in the data and the slope calculated is a poor indicator of the change in sales price over time. If R2 is large, say 0.7 or greater, then the model explains 70 percent or more of the variance in the data, and the slope of the regression line is a good indicator for quantifying the change in sales price over time. Regression models with low R2 values must be interpreted with caution. Often, knowledge and examination of factors not included in the regression model can help one understand why the regression provides a poor fit.

iv. Case I, II, and III Definitions

This report tests for effects of wind farms on property sales prices using three different models, or cases. All employ linear regression on six-month trailing averaged monthly residential sales data as outlined above.

Case 1 compares changes in the view shed and comparable community sales prices for the entire period of the study. If wind farms have a negative effect, we would expect to see prices increase slower (or decrease faster) in the view shed than in the comparable. Case 1 takes into account the wind farm on-line date only in that the data set begins three years before the on-line date. An appropriate comparable is important in this case in order that meaningful comparison of sale price changes over time can be made.

Case 2 compares property sales prices in the view shed before and after the wind farm in question came on-line. If wind farms have a negative effect, we would expect to see prices increase slower (or decrease faster) in view shed after the wind farm went on-line than before. Case 2 is susceptible to effects of macro-economic trends and other pressures on housing prices not taken into account in the model. Because Case 2 looks only at the view shed, it is possible that external factors change prices faster before or after the on-line date, and the analysis may therefore pick up factors other than the wind development.

Case 3 compares property sales prices in the view shed and comparable community, but only for the period after the projects came on-line. If wind farms have a negative effect, we would expect to see prices increase slower (or decrease faster) in view shed than comparable after the on-line date. Again, an appropriate comparable is important in this case in order that meaningful comparison of sale price changes over time can be made.

CHAPTER III. SITE REPORTS

SITE REPORT I: RIVERSIDE COUNTY, CALIFORNIA

A. PROJECT DESCRIPTION

The topography ranges from desert flats to arid mountains with views of snow capped peaks in winter - all of which encompass areas both in and out of the view shed.

The area has extreme elevation changes from the Palm Springs flats at an elevation of 450 feet, to the San Geronimo Pass at an elevation of 2,500 feet. The Pass cuts through the two peaks of Mt. San Geronimo to the north and Mt. San Jacinto to the southeast, and is five miles from the western edge of Palm Springs (15 to downtown), and about 80 miles east of Los Angeles.

FIGURE 1.1: VIEW OF WIND FARMS AT SAN GORGONIO PASS, RIVERSIDE COUNTY, CA

PHOTO BY DAVID F. GALLAGHER, 2001 - WWW.LIGHTNINGFIELD.COM

The projects are located in the San Geronimo Pass immediately west of the Palm Springs area in Riverside County, California. Developers installed 3,067 turbines from 1981 to 2001, with the tallest turbine at 63 meters (207 feet). Repowering projects built 130 modern turbines. They begin northwest of Palm Spring heading up Interstate 10 from Indian Avenue, then they extend more than 10 miles along the Pass up into the San Geronimo Mountains, along the Pass, and stop shortly before reaching Cabazon.

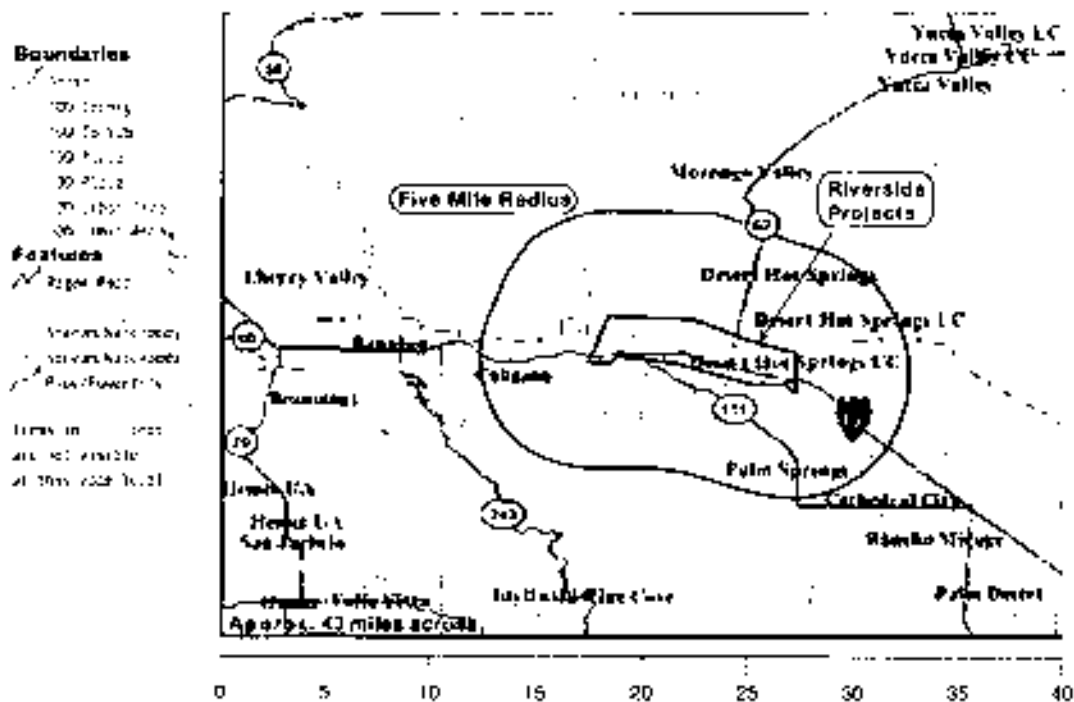

FIGURE 1.3 SAN GERONIMO, RIVERSIDE COUNTY, CALIFORNIA VIEW SHED
 (5 MILE RADIUS FROM PROJECT EDGE)
 MAP SOURCE: U.S. Census Bureau Website
 PROFILE LOCATION DETAILS: INTERVIEWS AND AERIAL PHOTOGRAPHS

The county is considered a metro area with 2 million population or more, but that is due to the population of the Los Angeles area. See Appendix 1 for a definition of rural urban continuum codes. The view shed represents fewer than 30,000 people.

C. ANALYSIS

i. Data

Real property sales data for 1996 to 2002 was obtained from First American Real Estate Solutions in Anaheim, CA. The dataset is quite detailed and contains many property and locational attributes, among them nine-digit zip code (ZIP+4) locations. Sales data was purchased for four zip codes encompassing the wind farm area and surrounding communities. These zip codes are Palm Springs (92262), White Water (92282), Cabazon (92230), and Banning (92220).

Sales for the following residential property types were included in the analysis: Condominiums, Duplexes, Mobile Homes, and Single-Family Residences. Upon initial analysis, of the 9105 data points analyzed, approximately 10 sales in the view shed had unusually high prices. Conversations with the Assessor's Office confirmed these were incorrect values for the data points. Correct values were obtained and the data corrected.

Projects that went on-line during the study period are the Cabazon, Enron, Energy Unlimited, Mountain View Power Partners I & II, and Westwind sites. Of these, two sites added 87 MW of repowered capacity in May 1999, two sites added 27 MW of new capacity in June 1999, and two sites added 66 MW of new capacity in October 2001.

ii. View shed Definition

All ZIP+4 regions within five miles of the wind turbines define the view shed. The location of the ZIP+4 regions were derived from the latitude and longitude of the ZIP+4 areas obtained from the U.S. Census TIGER database. The view shed includes the northwest portion of Palm Springs, Desert Hot Springs, and Cabazon, and 5,513 sales from 1996 to 2002. The view shed portion of northwest Palm Springs corresponds very closely to the boundaries of Palm Springs zip code 92262.

Interviews with State of California Palm Springs Regional Assessors Office were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Assessment District Supervisor Gary Stevenson's opinion, over 80 percent of Cabazon properties can see some wind turbines; over 80 percent of Desert Hot Springs properties can see some wind turbines; almost all of the properties on the outer edge of northwest Palm Springs can see some wind turbines, but due to foliage (mainly palm trees) and tall buildings, only five percent or less of the properties in the interior of Palm Springs can see any wind turbines.

iii. Comparable Selection

The comparable community was selected through interviews with State of California San Geronimo Regional Assessors Office personnel, as well as analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Selection of the comparable in this case was difficult, as the eastern side of the view shed is close to downtown Palm Springs, which is growing fairly quickly, while the western portion of the view shed, including Cabazon, is not growing quickly and has more stable housing sales prices. Tables 1.2 and 1.3 summarize the Census data reviewed. Because Census data by zip code is not available for 1990, we were unable to determine 1990 demographic statistics for the Palm Springs view shed, as it is not separable from the Palm Springs non-view shed area.

Based on his extensive experience in the area, Assessment District Supervisor Gary Stevenson suggested Banning and Beaumont in Riverside County, to the west of the wind farms, and Morongo Valley in San Bernardino County, to the north of the wind farms as appropriate comparables to the view shed area. Banning and Beaumont are visually separated from the wind farm area by a ridge, and Morongo Valley is separated by approximately seven miles distance.

In order to determine the most appropriate comparable community we looked at the demographics of 10 surrounding areas. The 92264 zip code area of Palm Springs to the south of north-west Palm Springs was initially considered as a comparable, but Supervisor Stevenson said that this area was closer to the metropolitan center and had significantly different demographics than the view shed area. Towns adjacent to Banning and Beaumont, including Hemet, San Jacinto, and Cherry Valley, were considered but rejected for use after discussion with Supervisor Stevenson. Upon examination of Census data, sales data availability, and review of Assessor comments, Banning was selected as the comparable, with a total of 3,592 sales from 1990 to 2002.

¹San Bernardino County.

iv. Analytical Results and Discussion

In all three of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, indicating that there is no significant evidence that the presence of the wind farms had a negative effect on residential property values. For Cases II and III, the on-line date is defined as the month the first wind project came on-line during the study period, May 1999.

In Case I, the monthly sales price change in the view shed is twice the monthly sales price change of the comparable over the study period. The Case I model provides a good fit to the data, with over 80 percent of the variance in the data explained by the linear regression. In Case II, the monthly sales price change in the view shed is 86 percent greater after the on-line date than before the on-line date. The Case II model provides a good fit to the data, with over two-thirds of the variance in the data explained by the linear regression. In Case III, the monthly sales price change in the view shed after the on-line date is 63 percent greater than the monthly sales price change of the comparable after the on-line date. The data for the full study period is graphed in Figure 1.4, and regression results for all cases are summarized in Table 1.4 below.

TABLE 1.4 RIVERSIDE COUNTY, CALIFORNIA: REGRESSION RESULTS

Projects: Cabazon, Enron, Energy Unlimited, Mountain View Power Partners I & II, Westwind					
Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data Comparable, all data	Jan 96 - Nov 02 Jan 96 - Nov 02	\$1,719.65 \$814.17	0.92 0.81	The rate of change in average view shed sales price is 2.1 times greater than the rate of change of the comparable over the study period.
Case 2	View shed, before View shed, after	Jan 96 - Apr 99 May 99 - Nov 02	\$1,062.83 \$1,978.88	0.68 0.81	The rate of change in average view shed sales price is 86% greater after the on-line date than the rate of change before the on-line date.
Case 3	View shed, after Comparable, after	May 99 - Nov 02 May 99 - Nov 02	\$1,978.88 \$1,212.14	0.81 0.74	The rate of change in average view shed sales price after the on-line date is 63% greater than the rate of change of the comparable after the on-line date.

D. Additional Interviewee Comments

Jack Norie of Desert Hot Springs, who provides tours of the wind projects, said that since 1998 there has been a discernable sense that more turbines were in the area. Norie felt that the 41 new turbines built high up along the nearest peaks facing Palm Springs near the intersection of Highway 111 and Interstate 10 on the north side, contributed to this impression. (These are possibly the Mountain View Power Partners II project with 37 turbines). Mr. Norie's descriptions of project locations and aerial photographs available from Microsoft's Terraserver and Mapquest, allowed us to determine project locations.

SITE REPORTS 2.1 AND 2.2: MADISON COUNTY, NEW YORK

A. PROJECT DESCRIPTION

Madison County has two wind farms meeting the criteria for analysis, Madison and Fenner. Because they are separated by distance, and have different on-line dates, each wind farm is analyzed separately. However, since they are in the same county and share the same comparable region, both analyses are presented in this section.

The Fenner turbines are sited in a primarily agricultural region southeast of Syracuse and southwest of Utica, with 20 turbines at 100 meters (328 feet). The Madison project is about 15 miles southeast of Fenner, and 2.5 miles east of Madison town with seven turbines standing 67 meters (220 feet).

Madison County is classified as a "county in a metro area with 250,000 to 1 million population." See Appendix 1 for a definition of rural/urban continuum codes. The view shed areas have a population less than 8,000.

Project Name	Completion Date	Capacity (MW)
Fenner Wind Power Project	2001	30.0
Madison Windpower	2000	11.6

C. ANALYSIS

i. Data

Real property sales data for 1997 to 2002 was purchased on CD-ROM from Madison County Real Property Tax Services in Wampsville, NY. The sales data was purchased for the townships and cities encompassing the wind farm areas and surrounding communities. The unit of analysis for this dataset is defined by either township or incorporated city boundaries. Though street addresses are included in the dataset, this analysis lacked the resources to identify the location of properties by street address.

In addition to basic sales data, the dataset included property attributes such as building style, housing quality grade, and neighborhood ratings. The CD-ROMs contained four files that required merging on a common field to create the composite database of all sales. A significant number of redundant, incomplete, and blank entries were deleted prior to analysis. Sales for the following residential property types were included in the analysis: one-, two-, and three-family houses, rural residences on 10+ acres, and mobile homes.

Upon initial analysis, of the 1,263 data points analyzed, approximately six sales in the Madison view shed had unusually high prices. Conversations with the Assessors Office confirmed four of these were valid sales, but that two were not. The invalid sales were eliminated from the analysis.

Projects that went on-line during the study period are the Madison wind farm, which went on-line September 2000 with a capacity of 11.6 MW, and the Fenner wind farm, which went on-line December 2001 with a capacity of 30 MW. The wind farms are approximately 15 miles apart.

ii. View Shed Definition

Two separate view sheds are defined for Madison County; one for each wind farm. A five-mile radius around the Madison wind farm encompasses the town of Madison and over 95 percent of Madison Township. The view shed also encompasses portions of three townships in Oneida County. However, due to lack of resources to identify the location of individual properties within townships, the Oneida townships were excluded from the analysis. The Madison view shed is defined as Madison town and all of Madison Township. The Fenner view shed is defined as all of Fenner, Lincoln, and Smithfield Townships, which are fully within a five-mile radius around the Fenner wind farm, with the exception of a small corner of Smithfield Township. The Madison and Fenner view sheds accounts for 219 and 453 sales over the study period, respectively.

Interviews with the State of New York Madison County Assessors Office were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Fenner Assessment District Supervisor Russell Cary's opinion, over 80 to 85 percent of Fenner properties can see some wind turbines, over 85 percent of Lincoln properties can see some wind turbines, over 75 percent of Madison properties can see some wind turbines, and approximately 60 percent of Smithfield properties can see some wind turbines. Cary said that in his opinion, only a few properties in Fenner Township, near Route 13, could not see some wind turbines.

iii. Comparable Selection

The comparable community was selected through interviews with State of New York Madison County Assessors Office personnel, as well as analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Tables 2.2 and 2.3 summarize the Census data reviewed. In order to determine the most appropriate comparable community, we looked at the demographics of 13 surrounding areas. Based on his experience in the area, Assessment District Supervisor Russell Cary suggested Lebanon, DeRuyter and Stockbridge Townships along with villages of DeRuyter, Munnsville and Hamilton, all in Madison County, as appropriate comparables for both view sheds. However, Cary added that Hamilton has higher property values than Madison because it is home to Colgate University. Upon examination of Census data, sales data availability, and review of Assessor comments, Lebanon, DeRuyter, Hamilton, Stockbridge Townships, and the Villages of DeRuyter and Munnsville were selected as the comparable for both view sheds, with a total of 591 sales from 1997 to 2002.

iv. Analytical Results and Discussion

In five of the six regression models, monthly average sales prices grew faster or declined slower in the view shed than in the comparable area. However, in the case of the underperformance of the view shed, the explanatory power of the model is very poor. Thus, there is no significant evidence in these cases that the presence of the wind farms had a negative effect on residential property values.

MADISON VIEW SHED

In Case I, the monthly sales price change in the view shed is 2.3 times the monthly sales price change of the comparable area the study period. However, the Case I model provides a poor fit to the data, with approximately 30 percent of the variance in the data explained by the linear regression. In Case II, the monthly sales price change in the view shed is 10.3 times greater after the on-line date than before the on-line date. However, the Case II model provides a poor fit to the data, with less than 30 percent of the variance in the data after the on-line date, and only 1 percent of the variance before the on-line date explained by the linear regression. In Case III, average monthly sales prices increase in the view shed after the on-line date, but decrease in the comparable region. The average view shed sales price after the on-line date increased at 3.2 times the rate of decrease in the comparable after the on-line date. The Case III model describes less than 30 percent of the variance in the view shed, but almost 90 percent of the variance in the comparable. The poor fit of the models, at least for the view shed, is partly due to a handful of property sales that were significantly higher than the typical view shed property sale. The data for the full study period is graphed in Figure 2.4, and regression results for all cases are summarized in Table 2.4 below.

TABLE 2.4 MADISON COUNTY, NEW YORK: REGRESSION RESULTS
PROJECT: MADISON

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 97 - Jan 03	\$576.22	0.29	The rate of change in average view shed sales price is 2.3 times greater than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 97 - Jan 03	\$245.51	0.34	
Case 2	View shed, before	Jan 97 - Aug 00	\$129.32	0.01	The rate of change in average view shed sales price after the on-line date is 10.3 times greater than the rate of change before the on-line date.

FIGURE 2.4 AVERAGE RESIDENTIAL HOUSING SALES PRICE FOR MADISON PROJECT
MADISON COUNTY, NEW YORK 1997-2003

FENNER VIEW SHED

In Case I, the monthly sales price change in the view shed is 50 percent greater than the monthly sales price change of the comparable over the study period. The Case I model explains approximately one-third of the variance in the data. In Case II, average monthly sales prices increase in the view shed prior to the on-line date, but decrease after the on-line date. The average view shed sales price after the on-line date decreased at 29 percent of the rate of increase before the on-line date. The Case II model provides a fair fit to the data before the on-line date, with half of the variance in the data explained by the linear regression, but a poor fit after the on-line date, explaining only 4 percent of the variance in the data. The poor fit is partly due to having only 14 months of data after the on-line date, which may not be enough data establish clear price trends in a housing market that exhibits significant price fluctuations over time. In Case III, average monthly sales prices decrease in both the view shed and comparable after the on-line date, with the view shed decreasing less quickly. The decrease in average view shed sales price after the on-line date is 37 percent less than the decrease of the comparable after the on-line date. The Case III model again describes only 4 percent of the variance in the view shed, but over 60 percent of the variance in the comparable. The data for the full study period is graphed in Figure 2.5, and the regression results are summarized in Table 2.5.

TABLE 2.5 MADISON COUNTY, NEW YORK: REGRESSION RESULTS
PROJECT: FENNER

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data Comparable, all data	Jan 97 - Jan 03 Jan 97 - Jan 03	\$368.47 \$245.51	0.35 0.34	The rate of change in average view shed sales price is 50% greater than the rate of change of the comparable over the study period.
Case 2	View shed, before View shed, after	Jan 97 - Nov 01 Dec 01 - Jan 03	\$587.95 -\$418.98	0.50 0.04	The rate of decrease in average view shed sales price after the on-line date is 29% lower than the rate of sales price increase before the on-line date.
Case 3	View shed, after Comparable, after	Dec 01 - Jan 03 Dec 01 - Jan 03	-\$418.98 -\$663.38	0.04 0.63	The rate of decrease in average view shed sales price after the on-line date is 37% less than the rate of decrease of the comparable after the on-line date.

FIGURE 2.5 AVERAGE RESIDENTIAL HOUSING SALES PRICE FOR FENNER PROJECT
MADISON COUNTY, NEW YORK 1997-2001

D. Additional Interviewee Comments

Madison County assessors Carol Brophy and Priscilla Suits said they have not seen any impact of the turbines on property values, and Suits added, "There's been no talk of any impact on values." Assessor Russell Cary noted that there were worries about views of the turbines, and that the project siting was designed such that the town of Cazenovia could not see the project – it rests just outside the five-mile perimeter view shed this study designed.

SITE REPORT 3: CARSON COUNTY, TEXAS

A. PROJECT DESCRIPTION

Situated in the middle of the Texas panhandle among large agricultural farms and small herds of cattle on fallow, 30 turbines stand at 70 meters (230 feet) high. Southwest of the project by 2.5 miles is White Deer town, which is 41 miles northeast of Amarillo.

The area is just about dead flat since Carson is right on the edge of the Texas High Plains. The general classification of the county is “completely rural or less than 2,500 urban population, but adjacent to a metro area.” See Appendix 1 for a definition of rural urban continuum codes. The view shed represents fewer than 1,200 people.

Project Name	Completion Date	Capacity (MW)
Llano Estacado Wind Ranch	2001	30

C. ANALYSIS

i. Data

Real property sales data for 1998 to 2002 was purchased in paper format from Carson County Appraisal District in Panhandle, TX. The sales data was purchased for the entire county, including the wind farm area and surrounding communities. The unit of analysis for this dataset is defined by census block and section and incorporated city boundaries. A detailed landowners map from for the County that identified every parcel, section, and block in the county was purchased. The Appraiser marked the exact parcel locations of the wind farms on the map, eliminating any estimation of the actual wind farm location.

The dataset included only a few property attributes, such as residence square footage and age of home. While the dataset included all sales of land, commercial property, and residential property, the analysis included only improved lots with residential housing, with a total of 369 sales over the study period. While there were no questions about unusual data points, the view shed had only 45 sales over the five years of data analyzed. This meant that many months had no sales in the view shed. While the six-month trailing average smoothed out most of the gaps, there was a seven-month gap in view shed data from August 2001 through February 2002. As a proxy for the missing data, the average of the two previous months with sales was used to fill in the gap. In addition, a few low value sales and a number of months with no sales contributed to a very low average sale price in the view shed between July 2000 and May 2001.

ii. View Shed Definition

View shed definition using the five-mile radius was straightforward given the land owner map, exact wind farm location, and one-mile reference scale on the map. The town of White Deer lies entirely within the view shed. The region of Skellytown lies just outside the edge of the five-mile radius, too far to be defined as view shed, but too close given the flat land and easily seen wind turbines to be considered as part of the comparable. Thus Skellytown, with a total of 16 sales, was excluded from the analysis. The view shed accounts for 45 sales over the study period.

Interviews with the State of Texas Carson County Appraisal District officers were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Appraiser Mike Darnell's opinion, 90 to 100 percent of White Deer residents can see the project.

iii. Comparable Selection

The comparable community was selected through interviews with State of Texas Carson County Appraisal District personnel, as well as analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Tables 3.2 and 3.3 summarize the Census data reviewed. In order to determine the most appropriate comparable community we looked at the demographics of three remaining residential areas in the county that were not part of the view shed and not excluded by being too close to the view shed.

Based on his experience in the area, Appraiser Mike Darnell suggested that Groom would be an appropriate comparable in the view shed area. However, Darnell said that homes in Fritch and Panhandle are more expensive, and have been increasing in value faster over time. Upon examination of Census data, sales data availability, and review of Assessor comments, all three residential areas, Fritch, Groom, and Panhandle were selected as the comparable, with a total of 224 sales from 1998 to 2002.

TABLE 3.2 CARSON COUNTY, TEXAS: 1990 CENSUS DATA

Year	View shed	Location	Population	Median household income	% Population below poverty level	Number housing units	Median value-owner-occupied housing unit
1990	Y	White Deer-Groom division	2,863	\$23,883	8%	1,319	\$34,700
1990	N	Parhandle division	3,713	\$28,569	10%	1,537	\$44,100
1990 COUNTY DEMOGRAPHICS			6,576	\$26,228	9%	2,856	\$39,400

TABLE 3.3 CARSON COUNTY, TEXAS: 2000 CENSUS DATA

Year	View shed	Location	Population	Median household income	% Population below poverty level	Number housing units	Median value-owner-occupied housing unit
2000	Y	White Deer-Groom CCD	2,702	\$36,117	9%	1,261	\$46,900
2000	N	Parhandle CCD	3,814	\$43,349	6%	1,554	\$60,400
2000 COUNTY DEMOGRAPHICS			6,516	\$39,733	7%	2,815	\$53,150

iv. Analytical Results and Discussion

In all three of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, indicating that there is no significant evidence that the presence of the wind farms had a negative effect on residential property values.

In Case I, the monthly sales price change in the view shed is 2.1 times the monthly sales price change of the comparable over the study period. The Case I model provides a fair fit to the view shed data, with almost half of the variance in the data explained by the linear regression. However, the model only explains one-third of the variance in the comparable data. In Case II, the monthly sales price change in the view shed is 3.4 times greater after the on-line date than before the on-line date. The Case II model provides a poor fit to the data prior to the on-line date, with a quarter of the variance in the data explained by the linear regression. However, the fit after the on-line date is good, with over 80 percent of the variance explained. In Case III, average monthly sales prices increase in the view shed after the on-line date, but decrease in the comparable region. The average view shed sales price after the on-line date increased at 13.1 times the rate of decrease in the comparable after the on-line date. The Case III model describes over 80 percent of the variance in the view shed, but provides a very poor fit with only 2 percent of the variance explained in the comparable. The data for the full study period is graphed in Figure 3.4, and regression results for all cases are summarized in Table 3.4 below.

**TABLE 3.4 CARSON COUNTY, TEXAS: REGRESSION RESULTS
PROJECT: LLANO ESTACADO WIND RANCH**

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result

CARSON COUNTY, TEXAS 1998-2002**

D. ADDITIONAL INTERVIEWEE COMMENTS

Carson County officers Mike Darnell, appraisal district officer, and Barbara Cooper, tax office, said most of the land in the view shed were farms, and that most residents in White Deer worked on the farms. Therefore, White Deer residents' interest in housing values was wholly dependent on their proximity to farms with no concerns for the wind towers, she said. Darnell added that most residents in White Deer liked the turbines because they brought new jobs to the area, and there has been no talk of dissent with the turbines.

The county's main claim to fame is it's the home of Pantex, the only nuclear armament production and disassembly facility in the U.S., according to Department of Energy's www.pantex.com website.

SITE REPORT 4: BENNINGTON COUNTY, VERMONT

A. PROJECT DESCRIPTION

One mile due south of Searsburg, atop a ridge, stand 11 turbines with 40-meter (131 foot) hub heights in a line running north-south. The solid, white, conical towers rise well above dense woods, but the black painted blades are virtually invisible – especially when in motion. The site is in Bennington County less than a mile west of Windham County, and is midway between the two medium-size towns of Bennington and Brattleboro.

The area is defined as a non-metro area adjacent to a metro area, though not completely rural and with a population between 2,500 and 19,999. See Appendix 1 for a definition of rural/urban continuum codes. The view shed has a population of fewer than 4,000.

Searsburg	1997	6

C. ANALYSIS

i. Data

Real property sales data for 1994 to 2002 was purchased in electronic form from Phil Dodd of VermontProperty.com in Montpelier, VT. Sales data was purchased for the townships and cities encompassing the wind farm area and surrounding communities, and was provided in two separate datasets. The first dataset, covering years 1994 through 1998, contained only annual average property sale prices and sales volumes, by town. No other locational data or property attributes were included. Property types from this dataset used in the analysis are primary residences and vacation homes, accounting for 1,584 sales.

The second dataset contained information on individual property sales from May 1998 through October 2002, and accounted for 2,333 sales. The unit of analysis for the second dataset is towns. Some street addresses were included in the property descriptions, but many of these were only partial addresses. Property types from this dataset used in the analysis are primary homes, primary condominiums, vacation condominiums, and camp or vacation homes. The Searsburg wind farm went on-line in February 1997, with a capacity of 6 MW, during the time when only annually averaged sales data was available.

ii. View Shed Definition

The view shed is defined by a five-mile radius around the wind farm, and encompasses four incorporated towns: Searsburg in Bennington county, and Dover, Sumner, and Wilmington in Windham County. Interviews with the State of Vermont Windham County Listers Office were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. According to Newfane town Lister Doris Knechtel, approximately 10 percent of the Searsburg homes can see the wind farm. Listers were unable to estimate what percentage of properties could see the wind farms in the other view shed towns. The final view shed dataset contained 1,055 sales from 1994 to 1998 and 1,733 sales for 1999 to 2002, for a total of 2,788 sales.

iii. Comparable Selection

The comparable community was selected through interviews with Phil Dodd of VermontProperty.com, interviews with State of Vermont Listers, as well as analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Tables 4.2 and 4.3 summarize the census data reviewed. In order to determine the most appropriate comparable community, we looked at the demographics of seven surrounding areas. Upon examination of Census data, sales data availability, and review of interview comments, Newfane and Whitingham in Windham County were selected as the comparable. The final comparable dataset contained 288 sales from 1994 to 1998 and 264 sales for 1999 to 2002, for a total of 552 sales from 1994 to 2002.

iv. Analytical Results and Discussion

In all three of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, indicating that there is no significant evidence that the presence of the wind farms had a negative effect on residential property values.

2000	Y	Dover village, Windham Cty.	1410	\$43,824	10%	2749	\$143,300	
2000	Y	Wilmington village, Windham Cty.	2,225	\$37,398	9%	2,232	\$120,100	
2000	VIEW SHED DEMOGRAPHICS			3,749	\$32,907	12%	5,046	\$116,700
2000	COMP	Newfane town, Windham Cty.	1,680	\$45,735	5%	977	\$123,600	
2000	COMP	Whitingham village, Windham Cty.	1,208	\$37,434	8%	802	\$111,200	
2000	COMPARABLE DEMOGRAPHICS			2,878	\$41,585	6%	1,779	\$117,400
2000	N	Halifax village, Windham Cty.	782	\$36,458	18%	493	\$98,800	
2000	N	Readsboro village, Bennington Cty.	803	\$35,000	7%	464	\$78,600	
2000	N	Stratton village, Windham Cty.	136	\$39,688	5%	1,091	\$125,000	
2000	N	Woodford village, Bennington Cty.	397	\$33,929	17%	355	\$91,300	
2000	N	Marlboro village, Windham Cty.	963	\$41,429	4%	495	\$150,000	

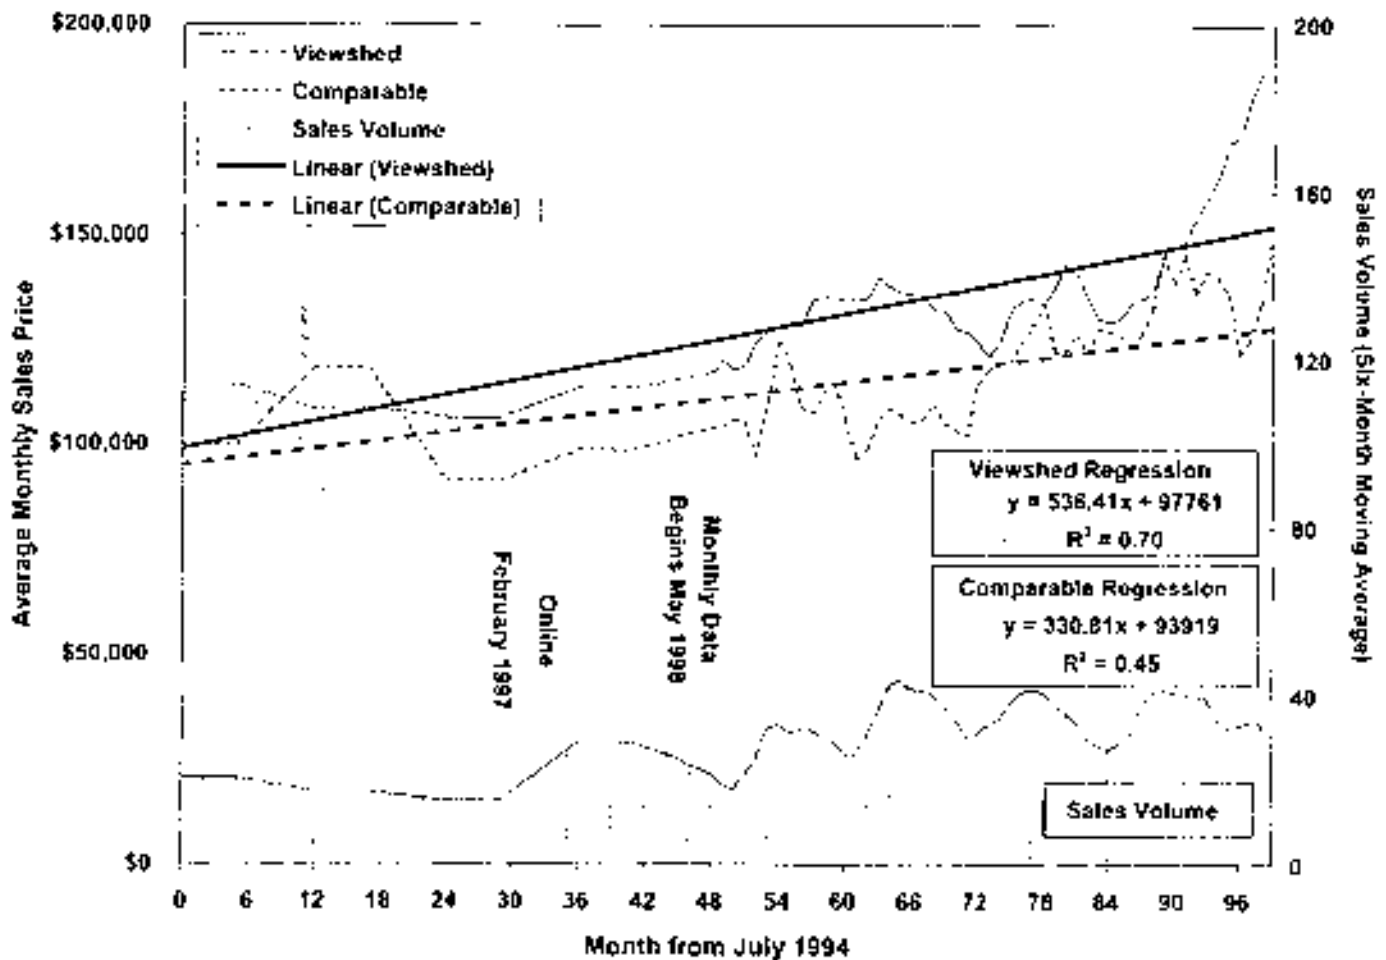

In Case I, the monthly sales price change in the view shed is 62 percent greater than the monthly sales price change of the comparable over the study period. The Case I model provides a reasonable fit to the view shed data, with 70 percent of the variance in the data for the view shed and 45 percent of the variance in the data for the comparable explained by the linear regression. In Case II, sales prices decreased in the view shed prior to the on-line date, and increased after the on-line date. The average view shed sales price after the on-line date increased at 2.6 times the rate of decrease in the view shed before the on-line date. The Case II model provides a good fit to the data, with 71 percent of the variance in the data for the view shed after the on-line date and 88 percent of the variance in the data before the on-line date explained by the linear regression. In Case III, average view shed sales prices after the on-line date are 18 percent greater than in the comparable. The Case III model describes over 70 percent of the variance in the data. The data for the full study period is graphed in Figure 4.4, and regression results for all cases are summarized in Table 4.4 below.

D. ADDITIONAL INTERVIEWEE COMMENTS

Newfane town Lister Doris Knechtel said the area has a wide cross section of home values, styles, and uses (permanent residential and vacation homes). The other primary community in the view shed was Wilmington, which Knechtel said was a resort destination with more turnover than Searsburg.

**TABLE 4-1 REGRESSION RESULTS, BENNINGTON AND WINDHAM COUNTIES, VT
PROJECT: SEARSBURG**

Model	Datasets	Dates	Base of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 94 - Oct 02	\$536.41	0.70	The rate of change in average view shed sales price is 62% greater than the rate of change of the comparable over the study period.

**FIGURE 4-4 AVERAGE RESIDENTIAL HOUSING SALES PRICE
BENNINGTON AND WINDHAM COUNTIES, VERMONT 1994-2002**

1. Vermont property assessments are organized differently from those being researched for this analysis. Assessors are called "towns" and operate per town - not on a county level. With small tax regions as appear elsewhere, local town offices are infrequently available, and it may be more difficult to answer questions via computer. The county government office confirmed that most Vermont offices did not have computers, but were in the process of receiving them as of October 2002.

SITE REPORT 5: KEWAUNEE COUNTY, WISCONSIN

A. PROJECT DESCRIPTION

The regional topography has slight elevation changes with some rolling hills, but is mostly cleared agricultural land with intermittent groves. The two major wind farm projects occupy three sites that are all within five miles of each other, two in Lincoln Township and one in Red River Township. There are several small communities in Red River and Lincoln Townships that primarily work the agricultural lands.

The projects, installed in 1999, consist of 31 turbines with hub heights of 65 meters (213 feet). The nearest incorporated towns are Algoma to the east, Kewaunee to the southeast, and Luxemburg to the southwest. The wind farms are roughly 15 miles from the center of the Green Bay metropolitan area, and 10 miles from the outer edges of the city. The area is defined as a non-metro area adjacent to a metro area, though not completely rural and with a population between 2,500 and 19,999. See Appendix 1 for a definition of rural urban continuum codes. The view shed has a population of approximately 3,000.

B. PROJECT TIMELINE

TABLE 5.1 WIND PROJECT HISTORY, KEWAUNEE COUNTY, WI

Project Name	Completion Date	Capacity (MW)
Lincoln (Gregorville, Lincoln Township)	1999	9.2
Rosiere (Lincoln and Red River Townships)	1999	11.2

C. ANALYSIS

i. Data

Real property sales data for 1996 to 2002 was purchased in paper and electronic form from the State of Wisconsin Department of Revenue Bureau of Equalization Green Bay Office. Sales data was obtained for the townships and cities encompassing the wind farm area and surrounding communities, and was provided in two separate datasets. The first dataset consisted of paper copy of Detailed Sales Studies for residential properties from 1994 to 1999. These contained individual property sales by month, year, and township or district. Parcel numbers were included, but no other locational data or property attributes were available. The second dataset consisted of electronic files containing residential property sales data for 2000 to 2002. This dataset contained no detailed property attributes, and only partial street addresses. The units of analysis for the combined dataset are townships and villages. After discussion with the Property Assessment Specialist, three unusually high value sales were removed from the view shed dataset. The final dataset included 624 sales from 1996 to 2002.

The Lincoln wind farm near Gregorville and the Rosiere wind farm on the Lincoln/Red River Township Border both went on-line June 1999, with capacities of 9.2 MW and 11.2 MW, respectively.

ii. View Shed Definition

The view shed is defined by a five-mile radius around the wind farms. Because the view sheds of the individual wind farm sites overlap, and because all wind farms went on-line at the same time, a single view shed was defined. It encompasses all of Lincoln and Red River Townships, and the incorporated town of Casco in Casco Township. To assist in the view shed definition, detailed plat maps for Lincoln and Red River Townships were obtained from the State of Wisconsin Bureau of Equalization Green Bay Office. These maps indicated every block and parcel in each township, and provided a one square mile grid to allow distance measurements. The location of each wind farm was marked on the map by the Bureau, and detailed aerial photos of each wind farm were also provided. This information allowed concise definition of the view shed area. Because only portions of Ahnapee, Luxemborg, and Casco Townships are in the view shed, these townships were excluded from consideration for either the view shed or comparable. The final view shed dataset contained 329 sales from 1996 to 2002.

Interviews with Kewaunee County Assessors were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. Assessor Dave Dorschner said 20 to 25 percent of Red River Township properties have views of the turbines. No one interviewed was able to estimate the percentage of properties in Lincoln Township or Casco Village with a view of the wind farms.

iii. Comparable Selection

The comparable community was selected through interviews with James W. Green, Bureau of Equalization Property Assessment Specialist, and analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Tables 5.2 and 5.3 summarize the Census data reviewed. In order to determine the most appropriate comparable community, we looked at the demographics of eight surrounding areas. Upon examination of Census

data, sales data availability, and review of interview comments, Carlton, Montpelier, and West Kewaunee Townships were selected as the comparable. The final comparable dataset contained 29% sales from 1996 to 2002.

TABLE 5.2 KEWAUNEE COUNTY, WISCONSIN: 1999 CENSUS DATA

Year	View shed	Location	Population	Median household income	% Population below poverty level	Number housing units	Median value-owner-occupied housing unit

iv. Analytical Results and Discussion

In all three of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, indicating that there is no significant evidence that the presence of the wind farms had a negative effect on residential property values. However, the fit of the linear regression is poor for all cases analyzed. Very low sales volumes, averaging 3.6 sales per month from 1996 to 1999, lead to large fluctuations in average sales prices from individual property sales. This contributes to the low R² values.

In Case I, the monthly sales price change in the view shed is 3.7 times the monthly sales price change of the comparable over the study period. However, the Case I model provides a poor fit to the view shed data, with 26 percent and 5 percent of the variance in the data explained by the linear regression in the view shed and comparable, respectively. In Case II, sales prices decreased in the view shed prior to the on-line date, and increased after the on-line date. The average view shed sales price after the on-line date increased at 3.5 times the rate of decrease in the view shed before the on-line date. The Case II model provides a poor fit to the data, with 32 percent of the variance in the data for the view shed after the on-line date and 2 percent of the variance in the data before the on-line date explained by the linear regression. In Case III, average monthly sales prices increase in the view shed after the on-line date, but decrease in the comparable region. The average view shed sales price after the on-line date increases 33 percent quicker than the comparable sales price decreases after the on-line date. The Case III model describes approximately a third of the variance in the data. The data for the full study period is graphed in Figure 5.4, and regression results for all cases are summarized in Table 5.4 below.

TABLE 5.4 REGRESSION RESULTS, KEWAUNEE COUNTY, WI

 Kewaunee County, Wisconsin 1996-2001

D. ADDITIONAL INTERVIEWER COMMENTS

Assessor Dave Dorschner said he has not seen an impact on property values except for those immediately neighboring the project sites. In the cases of neighboring property, he said some homes were sold because of visual and/or auditory distraction, but some of the properties were purchased speculatively in hope that a tower might be built on the property.

James W. Green, Wis. Bureau of Equalization property assessment specialist, also said he has not seen any impact of the turbines on property values. He added that he has seen greater property value increases in the rural areas than in the city because people were moving out of the Green Bay area opting for rural developments or old farmhouses.

SITE REPORT 6: SOMERSET COUNTY, PENNSYLVANIA

A. PROJECT DESCRIPTION

There are two major wind farms in Somerset County, Somerset and Green Mountain. They are about 20 miles due east of the wind farm in Fayette County, PA. The Somerset project has six turbines 64 meters (210 feet) high along a ridge crest east Somerset town. The Green Mountain project has eight turbines at 60 meters (197 feet). They are about 10 miles southwest of the Somerset project, and a mile west of Garret town.

The area is almost the same as Fayette County, but slightly less hilly -- dense populations of tall trees, frequent overcast, and primarily rural development. The area is classified as a "country in a metro area with fewer than 250,000." See Appendix 1 for a definition of rural-urban continuum codes. The view shed has a population of approximately 19,000.

Green Mountain Wind Farm	2000	10.4

C. ANALYSIS

i. Data

Real property sales data for 1997 to 2002 was obtained in electronic form from the State of Pennsylvania Somerset County Assessment Office in Somerset, PA. Sales data was obtained for the townships and cities encompassing the wind farm area and surrounding communities. The electronic files contain residential property sales data for 2000 to 2002. Residential types included in the analysis are homes, homes converted to apartments, mobile homes with land, condominiums, townhouses, and one mobile home on leased land. The dataset contained lot acreages and brief building descriptions, and some, but not all, records provided additional property attributes. As street addresses were not provided, the units of analysis for the dataset are townships and villages. The final dataset included 1,506 residential property sales from 1997 to 2002.

The Somerset wind farm went on-line October 2001 and the Green Mountain wind farm near Garrett went on-line May 2000, with capacities of 9.0 MW and 10.4 MW, respectively.

ii. View Shed Definition

The view shed is defined by a five-mile radius around the wind farms. Because the view sheds of the individual wind farm sites overlap, a single view shed was defined. It encompasses all of Somerset and Summit Townships, and the Garrett and Somerset Boroughs within these townships. Locational data for the wind farms was obtained from utility and wind industry web sites, and used in conjunction with maps and interviews with the Somerset County Mapping Department to identify the exact location and extent of the wind farms and view shed. Townships only partially within the view shed were excluded from consideration for either the view shed or comparable. The final view shed dataset contains 962 sales from 1997 to 2002.

Interviews with Somerset County Assessors were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Assessor Hudack's opinion, 10 percent of Somerset properties can see the turbines, and roughly 20 percent of Garrett properties have a view.

iii. Comparable Selection

The comparable community was selected through interviews with Assessors John Riley and Joe Hudack of the State of Pennsylvania Somerset County Assessment Office, and analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Tables 6.2 and 6.3 summarize the Census data reviewed. In order to determine the most appropriate comparable community we looked at the demographics of three surrounding areas. Upon examination of Census data, sales data availability, and review of interview comments, Conemaugh Township was selected as the comparable. The final comparable dataset contained 422 sales from 1997 to 2002.

iv. Analytical Results and Discussion

In all three of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, indicating that there is no significant evidence that the presence of the wind farms had a negative effect on residential property values.

In Case I, the monthly sales price change in the view shed is 90 percent greater than the monthly sales price change of the comparable over the study period. The Case I model provides a poor fit to the view shed data, with 30 percent of the variance in the data for the view shed and 7 percent of the variance in the data for the comparable explained by the linear regression. In Case II, the monthly sales price change in the view shed is 3.5 times greater after the on-line date than before the on-line date. The Case II model provides a poor fit to the data prior to the on-line date, with 37 percent of the variance in the data explained by the linear regression, but a reasonable fit after the on-line date, with 62 percent of the variance explained. In Case III, average monthly sales

prices increase in the view shed after the on-line date, but decrease in the comparable region. The average view shed sales price after the on-line date increased at 2.3 times the rate of decrease in the comparable after the on-line date. The Case III model describes 62 percent of the variance in the view shed, but only 23 percent of the variance in the comparable. The data for the full study period is graphed in Figure 6.4, and regression results for all cases are summarized in Table 6.4 below.

SOMERSET COUNTY, PENNSYLVANIA 1997-2002

D. ADDITIONAL INTERVIEWEE COMMENTS

Assessor Joe Hudack said he has not seen any impact on property values from wind farms. The turbines outside Somerset were also "not glaring," but could be seen from the PA Turnpike. The Green Mountain turbines outside Carret were noticeable, but because there were so few people residing there, he hasn't seen much housing turnover to have an opinion, he said.

SITE REPORT 7: BUENA VISTA COUNTY, IOWA

A. PROJECT DESCRIPTION

The geography of the view shed and comparable regions is flat with minimal elevation changes. The region is mostly cleared land for agricultural production, with trees along irrigation ditches or planted around homes for shade and wind dampening.

FIGURE 7.1 750 kW ZIONS WIND TURBINES 1.5 MILES EAST OF ALTA, IOWA
PHOTO COURTESY: WAVERLY LIGHT AND POWER © 2002

Surrounding Alta, Iowa and west of the town along the Buena Vista and Cherokee counties' border, 257 towers with 63 meter (207 ft) hub heights stand among agricultural farms and scattered homes. Project Storm Lake I comprises 150 towers around Alta extending 1.5-2.5 miles east and west, 1.5 miles south, and five miles north. Throughout the project, the turbines are consistently spaced 3.6 rotor diameters, or about 180 m (590 ft) apart. Project Storm Lake II comprises 107 towers, eight miles northwest of Alta, with several towers over the county border into neighboring Cherokee County. The exact location of all turbines was obtained from the Waverly Power and Light website. All towers have white color blades and hubs with either grey, ruffled towers or white solid towers. Solid red lights are required by the PAA on the nacelles of alternate turbines.

Buena Vista County is classified as an "urban population with 2,500 to 19,999 not adjacent to a metro area." See Appendix 1 for a definition of rural/urban continuum codes. This analysis defines two possible view sheds, depending on whether Storm Lake City is included in the analysis. Accordingly, the view shed has a population of either 4,000 or 13,000, depending on its definition.

B. PROJECT TIMELINE

TABLE 7.1 WIND PROJECT HISTORY, SOMERSET COUNTY, PA

Project Name	Completion Date	Capacity (MW)
Storm Lake I	1999	112.5
Storm Lake II	1999	80.2

C. ANALYSIS

i. Data

Real property sales data for 1996 to 2002 was obtained in electronic form from the Iowa State Assessors Office Website at www.iowassessors.com. Sales data was obtained for the townships and cities encompassing the wind farm area and surrounding communities. The electronic data gathered contains residential property sales prices, parcel numbers, street addresses, year built and square footage. The unit of analysis for this dataset is defined by either township or incorporated city boundaries. Though street addresses are included in the dataset, this analysis lacked the resources to identify the locations of properties by street address. The final dataset included 3,213 residential property sales from 1996 to 2002.

The Storm Lake II wind farm went on-line June 1999 and the Storm Lake I wind farm went on-line May 1999, with capacities of 112.5 MW and 80.2 MW, respectively.

ii. View Shed Definition

The view shed is defined by a five-mile radius around the wind farms. Because the view sheds of the individual wind farm sites overlap, and the on-line dates are within a month of each other, a single view shed was defined. Locational data for the wind farms was obtained from utility and wind industry web sites, and used in conjunction with maps and phone interviews to identify the exact location and extent of the wind farms and view shed. Townships only partially within the view shed were excluded from consideration for either the view shed or comparable.

Interviews with Somerset County Assessors were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Buena Vista County Assessor Ted Van Groenest's opinion, 100 percent of the properties in Alta have views of turbines, 75 percent of Nokomis Township have views, and five to 10 percent of Storm Lake City properties have views. However, he estimated that all the waterfront properties on the southeast side of Storm Lake can see turbines when looking northwest. Storm Lake City has a population of approximately 10,000, while Nokomis Township and Alta City have a combined population of approximately 2,000.

This report examines two cases for Buena Vista County.

Analysis #1: Storm Lake City Excluded from View Shed

For the first analysis, the view shed consists only of the village and township in which the wind turbines are located. In this case approximately 75 to 100 percent of the residential properties sold are within view of the wind farm, and are at most 3.5 miles from wind turbines, and in most cases much closer. We believe that if wind farms negatively effect property values, this effect would be strongest in this smaller radius view shed. The Analysis #1 view shed dataset contains 283 sales from 1996 to 2002.

Analysis #2: Storm Lake City Included in View Shed

For the second analysis, the view shed contains Storm Lake City, which is mainly within the five-mile view shed radius, in addition to Alta City and Nokomis Township as included in Analysis #1. Because Storm Lake City's population is five times larger than that of the Alta and Nokomis

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

combined, and because estimates are that roughly 5 percent of Storm Lake City properties can see the wind farms, we believe that any negative property value effects from the wind farms may be overshadowed by economic and demographic trends in Storm Lake City that are distinct from any effect the wind farms may have. The Analysis #2 view shed dataset contains 1,557 sales from 1996 to 2002.

iii. Comparable Selection

The comparable community was selected through interviews with Buena Vista County Assessor Ted Van Grooteest, and analysis of demographic data from the 1990 and 2000 U.S. Census for communities near but outside of the view shed. Tables 7.2 and 7.3 summarize the Census data reviewed. In order to determine the most appropriate comparable community, we looked at the demographics of five comparable communities. Upon examination of Census data, sales data availability, and review of interview comments, one city and four townships in Clay County, just to the north of Buena Vista County, were selected as the comparable. The comparables are Spencer City, and Meadow, Riverton, Sioux, and Summit Townships. The final comparable dataset contained 1,656 sales from 1996 to 2002.

iv. Analytical Results and Discussion

Analysis #1: Storm Lake City Excluded from View Shed

In all three of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, indicating that there is no significant evidence that the presence of the wind farms had a negative effect on residential property values.

In Case I, the monthly sales price change in the view shed is 18 percent greater than the monthly sales price change of the comparable over the study period. The Case I model provides a good fit to the data, with over two-thirds of the variance in the data explained by the linear regression. In Case II, the monthly sales price change in the view shed is 70 percent greater after the on-line date than before the on-line date. The Case II model provides a reasonable fit to the data, with over half of the variance in the data explained by the linear regression. In Case III, average view shed sales prices after the on-line date are 2.7 times greater than in the comparable. The Case III model describes over half of the variance in the data for the view shed, but only 23 percent of the variance for the comparable. The data for the full study period is graphed in Figure 7.4, and regression results for all cases are summarized in Table 7.4 below.

Analysis #2: Storm Lake City Included in View Shed

In all three of the regression models, monthly average sales prices grew slower in the view shed than in the comparable area.

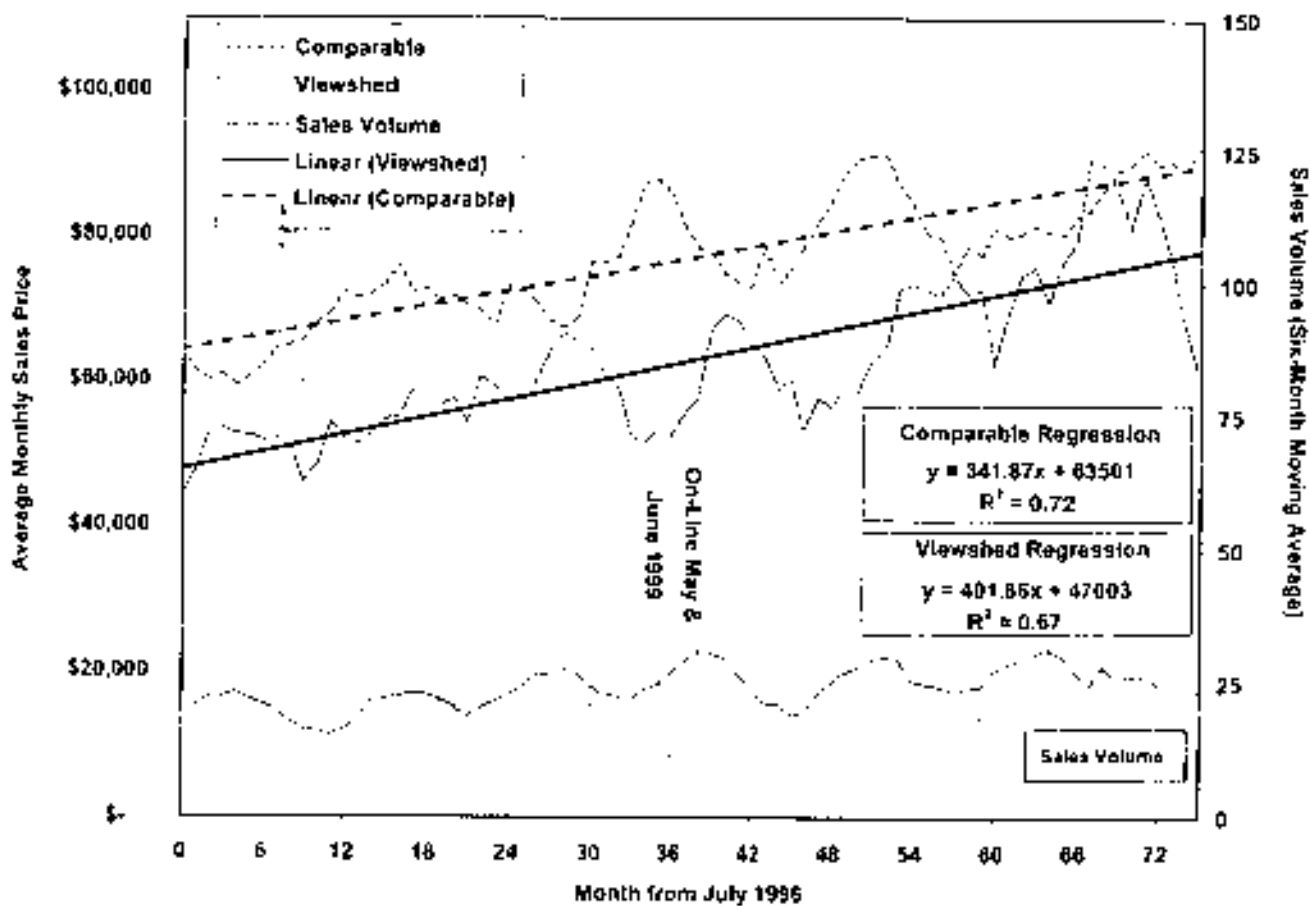

In Case I, the monthly sales price change in the view shed is 34 percent less than the monthly sales price change of the comparable over the study period. The Case I model provides a good fit to the data, with over 60 percent of the variance in the data explained by the linear regression. In Case II, the monthly sales price change in the view shed is 59 percent less after the on-line date than before the on-line date. The Case II model explains over half of the variance in the data prior to the on-line date explained, but only 27 percent of the variance after the on-line date. In Case III, average view shed sales prices after the on-line date are 22 percent lower than in the comparable.

The Effect of Wind Development on Local Property Values

The Case III model provides a poor fit to the data, explaining less than 30 percent of the variance for the data. The data for the full study period is graphed in Figure 7.5, and regression results for all cases are summarized in Table 7.5 below.

**TABLE 7.4 REGRESSION RESULTS, BUENA VISTA COUNTY, IA
PROJECTS: STORM LAKE I & II (WITHOUT STORM LAKE CITY)**

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 96 - Oct 02	\$401.86	0.67	The rate of change in average view shed sales price is 18% greater than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 96 - Oct 02	\$341.87	0.72	
Case 2	View shed, before	Jan 96 - Apr 99	\$370.52	0.51	The rate of change in average view shed sales price is 70% greater after the on-line date than the rate of change before the on-line date.
	View shed, after	May 99 - Oct 02	\$631.12	0.53	
Case 3	View shed, after	May 99 - Oct 02	\$631.12	0.53	The rate of change in average view shed sales price after the on-line date is 2.7 times greater than the rate of change of the comparable after the on-line date.
	Comparable, after	May 99 - Oct 02	\$234.84	0.23

BUENA VISTA COUNTY, IOWA 1996-2002

D. ADDITIONAL INTERVIEWEE COMMENTS

Brewer Vista County Assessor Ted Van Groenest said the comparable area around Spencer City in the northern neighboring county, Clay, would have higher property values because of its proximity to recreational lakes to the north, but that the two areas' property values rose at equal rates. He added that the predominate business mix was similar, but that the productive value of the land in Clay might be a little higher.

Between October 2002 and March 2003 the following information was obtained through other interviews with Groenest:

- o Most of the residences at the Lake Creek Country Club, a golf course community located just west of Storm Lake City (between the city and the wind farms), have views of the towers. Several towers are one-half mile north and southwest of the Country Club. The assessor owns a home at the Country Club.
- o In the assessor's opinion, the wind projects have no impact on property values. According to the assessor, the only issue that influences prices is the school district.
- o There is also a hog farm on the west side of Storm Lake - the same direction as the wind projects. Groenest said the property values did not change around the hog farm.

SITE REPORT 8: KERN COUNTY, CALIFORNIA

A. PROJECT DESCRIPTION

The Tehachapi Mountains stretch northeast and southwest with Tehachapi City and neighboring communities seated within a flat valley inside the range. Despite the arid climate, Tehachapi's elevation of 4,000 feet affords it four seasons. This region is known for its extensive wind farm development, which has been ongoing for over two decades.

FIGURES 8.1 – 8.2: VIEWS OF THE TEHACHAPI REGION WIND FARMS
TOP PHOTO COURTESY JEAN-CLAUDE GILSON © 2008 - BOTTOM PHOTO COURTESY WINDFARM INC. © 2008

Between 1981 and 2002 developers installed 3,569 towers with varied hub heights up to 55 meters (180.5 feet), and repowered six sites with 199 towers between 1997 and 2002. The projects nestle within the Tehachapi pass five miles east of Tehachapi City, through the Tehachapi mountains, and scatter along the east face just as Highway 58 drops sharply southeast toward Mojave and California cities bordering the Mojave Desert. The wind farm locations are shown in the regional area map, Figure 8.3, and view shed map, Figure 8.4, below.

To the east of the mountains are the cities of Mojave, California, and Richmond. The incorporated limits of these cities are all approximately three to four miles from the base of the range, where the Mojave Desert begins.

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

Foliage is patchy with many areas covered in wild, dry grasses. Juniper, and Cottonwood much like the terrain between Albuquerque and Santa Fe, New Mexico. However, there are some green portions with dense grasses allowing for cattle grazing or equestrian spreads.

Although Kern County is classified as a "county in a metro area with 250,000 to 1 million population," the view shed has a population of less than 15,000. See Appendix 1 for a definition of rural urban continuum codes. Also, Tehachapi is 40 miles to the nearest metro area of Bakersfield, and 115 miles to Los Angeles.

C. ANALYSIS

i. Data

Real property sales data for 1996 to 2002 was obtained from First American Real Estate Solutions in Anaheim, CA. The dataset is quite detailed and contains many property and locational attributes, among them 9-digit zip code (ZIP+4) locations. Sales data was purchased for two zip codes encompassing the wind farm area and surrounding communities. These zip codes are Mojave (93501) and Tehachapi (93561).

Sales for the following residential property types were included in the analysis: single-family residences, condominiums, apartments, duplexes, mobile homes, quadruplexes, and triplexes. Of 21 apartment sales in the database, five in the view shed had unusually high sales prices. After discussion with the local Assessor, it was determined that these did not represent single sale data points, and they were eliminated from the analysis. A total of 2,867 properties are used in the analysis.

Projects that went on-line during the study period are the Cameron Ridge, Pacific Crest, and Oak Creek Wind Power Phase II sites. All three are repowering projects, with installed capacities of 56 MW, 45 MW, and 23 MW, respectively. Cameron Ridge went on-line March 1999, and the other two came on-line June 1999.

ii. View Shed Definition

All ZIP+4 regions within 5 miles of the wind turbines define the view shed. The location of the ZIP+4 regions were derived from the latitude and longitude of the ZIP+4 areas obtained from the U.S. Census TIGER database. Because the view sheds of the individual wind farm sites overlap, and because all projects went on-line within three months of each other, a single composite view shed is defined. The view shed is approximated by two rectangles that overlap the combined area swept out by a five-mile radius from each wind farm location.

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

Locational data for the wind farms was obtained from utility and wind industry web sites, and used in conjunction with detailed block maps, wind farm site maps, topographic maps and interviews to identify the exact location and extent of the wind farms and the composite view shed. The final view shed dataset contains 745 sales from 1996 to 2002.

Interviews with Kern County Assessors were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. Assessor Ron Stout said 50 to 60 percent of residents within Tehachapi City could see the turbines, but the Golden Hills area was too far and had views only if one intentionally tried to see them. He said about 30 percent of residents in the northwest corner of Mojave (north of Purdy Avenue and West of the Airport) could see turbines.

iii. Comparable Selection

The comparable community was selected through extensive interviews with Assessor Ron Stout of the State of California Kern County Assessment Office and analysis of topographic and site maps. Because the U.S. Census does not provide Census data at the resolution of individual ZIP+4 regions, we were unable to use Census data as part of the comparable selection process in this case. Based on review of the Assessor interviews, the ZIP+4 regions in Golden Hills, Bear Valley Springs, Stallion Springs and the central and southeastern portions of Mojave, all within Mojave zip code 93501 and Tehachapi zip code 93561, were selected as the comparable. The final comparable dataset contained 2,122 sales from 1996 to 2002.

iv. Analytical Results and Discussion

In one of the regression models, monthly average sales prices grew faster in the view shed than in the comparable area, and in two of the regression models it did not.

In Case I, the monthly sales price change in the view shed is 28 percent less than the monthly sales price change of the comparable over the study period. The Case I model provides a good fit to the view shed data, with over 70 percent of the variance in the data explained by the linear regression. In Case II, the monthly sales price change in the view shed is 38 percent greater after the on-line date than before the on-line date. The Case II model provides a good fit to the post on-line data, with 75 percent of the variance in the data explained by the linear regression. For the pre-on-line period, the regression explains 44 percent of the variance in the data. In Case III, average view shed sales prices after the on-line date are 29 percent less than in the comparable. The Case III model provides a good fit to the data, with 75 percent of the variance in the view shed data and 95 percent of the variance in the comparable data explained by the regression. The data for the full study period is graphed in Figure 5.4, and regression results for all cases are summarized in Table 8.2 below.

D. ADDITIONAL INTERVIEWEE COMMENTS

Assessor Stout also said that Mojave has not seen any new residential development in eight years. Both Stout and Assessor James Maples said they have not seen any impact of the farms on property values. However, Maples said the area was so agricultural or lightly populated that it would be hard to isolate price changes due to the wind projects. Maples, added that over 30 years of wind project development – an industrial cement manufacturer, among other projects, was built close to Tehachapi on the east. The cement plant spewed out dust for 10 years or more until county and federal government inspectors required upgrades 15 years ago, said Stout.

Tehachapi is the busiest single-tracked (locomotive) mainline in the world, according to the Tehachapi Chamber of Commerce. It runs through the Tehachapi Mountains between Mojave and Bakersfield. Of other notable businesses, Tehachapi has a manufacturing plant for GE Wind Energy (formerly Zond) wind turbines.

TABLE 8.2 REGRESSION RESULTS, KERN COUNTY, CA
PROJECTS: PACIFIC CREST, CAMERON RIDGE, OAK CREEK PHASE II

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Jan 96 - Dec 02	\$492.38	0.72	The rate of change in average view shed sales price is 28% less than the rate of change of the comparable over the study period.
	Comparable, all data	Jan 96 - Dec 02	\$684.16	0.74	
Case 2	View shed, before	Jan 96 - Feb 99	\$668.16	0.44	The rate of change in average view shed sales price is 38% greater after the on-line date than the rate of change before the on-line date.
	View shed, after	Mar 99 - Dec 02	\$786.00	0.75	
Case 3	View shed, after	Mar 99 - Dec 02	\$786.60	0.75	The rate of change in average view shed sales price after the on-line date is 29% less than the rate of change of the comparable after the on-line date.
	Comparable, after	Mar 99 - Dec 02	\$1,115.10	0.95	

FIGURE 8.1 AVERAGE RESIDENTIAL HOUSING SALES PRICE

KERN COUNTY, CALIFORNIA 1996-2002

SITE REPORT 9: FAYETTE COUNTY, PENNSYLVANIA

A. PROJECT DESCRIPTION

Although the area is famous for being the home of Frank Lloyd Wright's Falling Water House built for a wealthy Pittsburgh family, much of the area is low-income and rural. The 10 turbines (rising 70 meters (230 feet)) were built along a ridge on the border of Stewart and Springfield Townships, and run north/south against the county border with Somerset. The land is owned primarily by one family who rents some of the acreage to a petroleum pumping company and for the turbines.

The area is very hilly with densely populated tall trees. The project site is approximately 62 miles from Pittsburgh with several ski lodges in the vicinity. The local economy is primarily agricultural or tourism related.

The view shed area of Springfield and Stewart Townships is rural with a combined population less than 2,000 although the county is classified as a "fringe county of a metro area with 1 million+ population or more." See Appendix 3 for a definition of rural/urban continuum codes. This discrepancy is because the southeastern periphery of suburban Pittsburgh creeps a little into northwest Fayette. The view shed is at least 62 miles from downtown Pittsburgh.

B. PROJECT TIMELINE

TABLE 9.1 WIND PROJECT HISTORY, FAYETTE COUNTY, PA

Project Name	Completion Date	Capacity (MW)
Mill Run Windpower LLC	2001	15.0

C. ANALYSIS

i. Data Source

Real property sales data for 1998 to 2002 was obtained electronically from the Fayette County Assessment Office Website, www.fayetteproperty.org/assessor. The dataset contains all property sales in Stewart and Springfield Townships. The sales volume is the smallest of all areas analyzed, with only 89 sales over the five-year period studied. The wind farm went on-line October 2001, with an installed capacity of 15 MW.

Complete addresses and detailed sales data are available on the website only by clicking on each parcel individually. However, there is no parcel map of the entire township to help identify parcel locations. We combined over 50 local parcel maps into one composite parcel map for the view shed, and used this in combination with street maps to identify the view shed and non-view shed areas.

ii. View Shed Definition

The view shed is defined by a five-mile radius around the wind farm. The view shed covers the eastern portion of both Springfield and Stewart Townships in Fayette County. The five-mile radius also covers portions of Lower Turkey Foot, Upper Turkey Foot, and Middlecreek Townships in Somerset County. Because the Somerset County Townships are only partially in the view shed, and because the Somerset data we obtained is identified primarily by township or city, these areas are not included in the analysis. The view shed is therefore defined as the portions of Springfield and Stewart Townships falling within the five-mile radius. The view shed accounts for 39 sales over the study period.

Interviews with the State of Pennsylvania Fayette County Assessors Office were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Fayette County Chief Assessor James A. Hercik's opinion, 10 to 20 percent of residents have views of the turbines.

iii. Comparable Selection

The comparable community was selected based on the availability of parcel-level data and through interviews with Fayette County Chief Assessor James A. Hercik. Assessor James Hercik said properties to the west of the view shed had no views of the wind turbines. Upon examination of sales data availability and review of Assessor comments, the western portions of Springfield and Stewart Townships, outside the five-mile view shed radius, were selected as the comparable, with a total of 50 sales from 1997 to 2002.

Demographic data from the 1990 and 2000 U.S. Census for Springfield and Stewart Townships was gathered, but not used because both the view shed and comparable are in the same township. Tables 9.2 and 9.3 summarize the Census data reviewed.

TABLE 9.2 FAYETTE COUNTY, PENNSYLVANIA: 1990 CENSUS DATA

Year	View shed	Location	Population	Median household income	% Population below poverty level	Number housing units	Median value-owner-occupied housing unit
1990	partial	Springfield Township	2,958	\$15,686	28%	1,137	\$40,200
1990	partial	Stewart Township	734	\$18,235	24%	331	\$42,500
VIEW SHED DEMOGRAPHICS			3,702	\$16,961	26%	1,468	\$41,350

TABLE 9.3 FAYETTE COUNTY, PENNSYLVANIA: 2000 CENSUS DATA

Year	View shed	Location	Population	Median household income	% Population below poverty level	Number housing units	Median value-owner-occupied housing unit
2000	partial	Springfield Township	3,111	\$29,133	22%	1,283	\$57,400
2000	partial	Stewart Township	743	\$32,917	11%	338	\$64,000
VIEW SHED DEMOGRAPHICS			3,854	\$31,026	16%	1,621	\$60,700

iv. Analytic Results and Discussion

In two of the three regression models, monthly average sales prices grew faster or declined slower in the view shed than in the comparable area. However, in the case of the underperformance of the view shed, the explanatory power of the model is very poor. Thus, there is no significant evidence in these cases that the presence of the wind farms had a negative effect on residential property values.

In Case I, the monthly sales price increase in the view shed is only 24 percent that of the comparable over the study period. However, the Case I model provides a poor fit to the view shed data, with only two percent of the variance in the data for the view shed and 24 percent of the variance in the data for the comparable explained by the linear regression. In Case II, sales prices decreased in the view shed prior to the on-line date, and increased after the on-line date. The average view shed sales price after the on-line date increased at 3.8 times the rate of decrease in the view shed before the on-line date. The Case II model provides a poor fit to the data, with less than one-third of the variance in the data explained by the linear regression. In Case III, average view shed sales prices after the on-line date are 13.5 times greater than in the comparable. However, the Case III model describes only 32 percent of the variance in the view shed data, and none of the variance in the comparable data. The data for the full study period is graphed in Figure 9.4, and regression results for all cases are summarized in Table 9.4 below.

The poor fit of the model, as evidenced by the low R² values, is partly due to the very small sales volume, on average only 2.1 sales per month in the view shed and comparable combined. As can be seen from Figure 9.4, the small sales volume leads to very high variability in average sale price from month to month. In addition, for regressions fit to data after the on-line date, only 13 months' sales data was available, amounting for 18 sales total, which leads to the caveat that these results should be viewed carefully.

TABLE 9.4 FAYETTE COUNTY, PENNSYLVANIA: REGRESSION RESULTS
PROJECT: MILL RUN

Model	Dataset	Dates	Rate of Change (\$/month)	Model Fit (R ²)	Result
Case 1	View shed, all data	Dec 97-Dec 02	\$115.96	0.02	The rate of change in average view shed sales price is 24% of the rate of change of the comparable over the study period.
	Comparable, all data	Dec 97-Dec 02	\$479.20	0.24	
Case 2	View shed, before	Dec 97 - Nov 01	-\$413.68	0.19	The rate of change in average view shed sales price after the on-line date increased at 3.8 times the rate of decrease before the on-line date.
	View shed, after	Oct 01-Dec 02	\$1,562.79	0.32	
Case 3	View shed, after	Oct 01-Dec 02	\$1,562.79	0.32	The rate of change in average view shed sales price after the on-line date is 13.5 times greater than the rate of change of the comparable after the on-line date.
	Comparable, after	Oct 01-Dec 02	\$115.86	0.00	

FIGURE 9.4 AVERAGE RESIDENTIAL HOUSING SALES PRICE
FAYETTE COUNTY, PENNSYLVANIA 1998-2001

D. ADDITIONAL ASSESSOR COMMENTS

James A. Herick, Fayette County chief assessor/director of assessments, said he has not seen any impact of the wind farms on property values, with the exception that the assessed value of properties with turbines went up. He also noted that on the same property as the turbines are on, there are natural gas wells, which additionally impact valuations. Finally, Herick said that often, sales in the view shed were family-to-family sales that may reflect sales prices lower than assessed value.

SITE REPORT: PROJECTS EXCLUDED FROM ANALYSES

Of the 27 projects selected for analysis, four were excluded from analysis because there were not enough sales in the view shed for statistical analysis; one was excluded because comparable data was not available at time of publication of this report; and an additional 12 projects were excluded because property sales data was unavailable, not readily available, or because there were not enough sales in the view shed for statistical analysis. Table 51 below summarizes the reasons for project exclusion from analysis.

TABLE 51: SUMMARY OF PROJECTS EXCLUDED FROM ANALYSES

I. Data acquired, but insufficient for analysis		
County	State	Reason for Exclusion
Logan	CO	Not enough sales to make a valid judgment (5 Sales)
Worth	IA	Not enough sales to make a valid judgment (38 sales over 7 years)
Umatilla	OR	Not enough sales to make a valid judgment (26 sales)
Howard	TX	Comparable data not acquired at time of publication (1,896 view shed sales)
Upton	TX	Not enough sales to make a valid judgment (7 sales)
II. Data not acquired		
County	State	Reason for Exclusion
Ward	CO	Not enough sales to make a valid judgment
Cerro Gordo	IA	No electronic data - accessible in office on paper only
Gray	KS	State law prohibits access to information
Pipestone	MN	No electronic data - accessible in office on paper only and not enough sales
Lincoln	MN	No electronic data - accessible in office on paper only
Gilliam	OR	No electronic data - accessible in office on paper only
Cookson	TX	No electronic data - accessible in office on paper only
Pecos	TX	No electronic data - accessible in office on paper only - and no sales in view shed
Taylor	TX	No electronic data - accessible in office on paper only
Benton	WA	Not enough sales to make a valid judgment (Project came on-line in 2002)
Walla Walla	WA	No sales in the view shed since project completion
Iowa	WI	No electronic data - accessible in office on paper only
Carbon	WY	State law prohibits access to information

I. DATA ACQUIRED, BUT INSUFFICIENT FOR ANALYSIS

County State Reason for Exclusion

Logan CO Not enough sales to make a valid judgment (Five Sales)

Years Reviewed: 1996 to 2002

Assessor Comments: Assessor Ann Rogers-Ridnour said her office has seen no impact from the wind project, and that it was hard gauge because there are so few sales.

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUES

Worth IA Not enough sales to make a valid judgment (38 sales over seven years)

Years Reviewed: 1996 to 2002

Assessor comments: Assessor said the project was surrounded only by agricultural land, that it was hard to pinpoint house locations on maps if any because addresses are vague, and that they felt the wind projects have been welcomed.

Umatilla OR Not enough sales to make a valid judgment (28 sales)

Years Reviewed: 1995 to 2002

Assessor comments: Assessor Lee Butler said there were only 28 sales in view shed.

Howard TX Comparable not available at time of publication

Years Reviewed: 1996 to 2002

The exact location of the Big Spring wind farm in Howard County, TX, and thus definition of the view shed, was elusive. While site maps with individual turbine locations were obtained, they were hand drawn and not to scale. Interviews with county Assessors and on-site operations staff yielded conflicting descriptions of the exact location of the turbines. In the end, the wind farm location was fixed in an interview with one of the original site developers, Mark Haller of Zilkha Inc. According to Mr. Haller, the turbine towers reach out far away from the Big Spring, but the closest one is only 100 yards or so from the third tee of a golf course on the south side of town – close enough for golfers often take chip shots at it.

The view shed covers portions, but not all of, the three school districts in the county: Coahoma, Big Spring, and Forsan. Approximately 70 percent of Big Spring City, all of Coahoma City, and none of Forsan City are within the view shed. Because this project lacks the resources to identify every property by street address, the view shed is defined to include all of Big Spring City, which is equivalent to using a six-mile radius view shed instead of a five-mile radius view shed for this case only. The final view shed dataset contains 1,896 sales from 1996 to 2002.

Interviews with Howard County Assessors were conducted by phone to determine what percentage of residential properties in the view shed can see all or a portion of the wind turbines. In Chief Assessor Keith Tominic's opinion, 30 percent of Big Spring City properties can see the turbines. Mr. Haller added that due to the various plateaus surrounding Big Spring, there are portions of the town that cannot see the turbines.

The selection of an appropriate comparable for Big Spring is difficult because the area has experienced an economic downturn and loss of jobs for a number of years. According to Howard County Chief Assessor Keith Tominic, the two major employment categories in the Big Spring are agriculture and petroleum extraction. Due to a 10-year drought in the region, crop yields are severely reduced, with significant economic impacts for the city. Additionally, depletion of petroleum resources has led to the closing of wells and economic downturn in the local petroleum industry.

Because the view shed for Big Spring was defined very late in the process of producing this report, data for a comparable has not yet been obtained.

Upton TX Not enough sales to make a valid judgment (Seven sales)

Years Reviewed: 1996 to 2002

Assessor comments: Chief Appraiser Shari Stevens said no sales near southwest Mesa, and only seven sales near the King Mountain project.

II. DATA NOT ACQUIRED

County _____ State _____ Reason for Exclusion

Weld _____ CO _____ No enough sales to make a valid judgment

Years Reviewed: 1996 to 2002

Assessor comments: Office staff said there were very few people in the project area and didn't think anybody could see it

Cerro Gordo _____ IA _____ No electronic data - accessible in office on paper only

Years Reviewed: 1996 to 2002

Assessor comments: Assessor said we were the third group to call them about the same question and that they've looked into every way they could to parse their data, and could find no proof that there was any impact on county property values

Gray _____ KS _____ State law prohibits access to information

Years Reviewed: 1996 to 2002

Assessor comments: Assessor Jerry Dewey said area had only small populations and that most land was agricultural; therefore he said they have seen no impact, primarily because the land is assessed for productive use.

Pipestone _____ MN _____ No electronic data - accessible in office on paper only - and not enough sales

Years Reviewed: 1991 to 2002

Assessor comments: Interim Assessor "Earley" said he's not seen any impact on property values. Also, he added that there haven't been enough sales to make a judgment call, and all property surrounding the project is agricultural land which is valued on productive use (so unless the turbines were on the property itself, then the property value would not go up).

Lincoln _____ MN _____ No electronic data - accessible in office on paper only

Years Reviewed: 1991 to 2002

Assessor comments: Assessor "Bruce" (last name unavailable) said the project was a "non-issue" and has not seen any impact on values. Specifically, the projects were welcomed and some people tried to have the turbines built on their land.

Gilliam _____ OR _____ No electronic data - accessible in office on paper only

Years Reviewed: 1997 to 2002

Assessor comments: Assessor Pat Shaw said area around project had a population less than 700 all living dispersed among agricultural land. Also, he expressed no sense of impact on property values

Culberson _____ TX _____ No electronic data - accessible in office on paper only

Years Reviewed: 1992 to 2002

Assessor comments: Appraiser Sally Carrasco said they've been very happy with the wind farms. She added that because they have a terrible economy, she wasn't sure if they would even have a town were it not for the revenue from turbines that support the schools.

Pecos _____ TX _____ No electronic data - accessible in office on paper only - and no sales in view shed

Years Reviewed: 1997 to 2002

Assessor comments: Assessor Santa S. Acosta said there were no residences with a view, and that there are so few sales in general that the area wasn't due for re-appraisal until 2005.

THE EFFECT OF WIND DEVELOPMENT ON LOCAL PROPERTY VALUESTaylor TX No electronic data - accessible in office on paper only

Years Reviewed: 1997 to 2002

Assessor comments: Assessor Ralf Anders said no homes had a view.

Benton WA Not enough sales to make a valid judgment.

(Project came on-line in 2002)

Years Reviewed: 1996 to 2002

Assessor comments: Office clerk "Harriet" said they only have the past three months of data in electronic form; everything else is in paper and a person must go in office to search records.

Walla Walla WA No sales in the view shed since project completion

Years Reviewed: 1996 to 2002

Assessor comments: Walla-Walla County Assessor Larry Shelley said there have been no sales since the wind project was built.

Iowa WI No electronic data - accessible in office on paper only

Years Reviewed: 1996 to 2002

Assessor comments: Assessor said only small village areas had views, but that the wind projects were welcomed. -Assessor specifically made a comment that a bowling alley has built a small tourist attraction around the project.

Carbon WY State law prohibits access to information

Years Reviewed: 1996 to 2002

Assessor comments: Assessor Darrell Stubbs said that although it is illegal to release individual property information, he has seen no impact on values. Specifically, he noted if any impact occurred, property values have risen because the population is so small that the infusion of a few jobs from the project in the area is enough to raise prices.

APPENDIX I. COUNTY CLASSIFICATION DESCRIPTIONS

U.S. DEPARTMENT OF AGRICULTURE, ECONOMIC RESEARCH SERVICE RURAL-URBAN CONTINUUM CODES

Metro counties:	
0	Central counties of metro areas of 1 million population or more.
1	Fringe counties of metro areas of 1 million population or more.
2	Counties in metro areas of 250,000 to 1 million population.
3	Counties in metro areas of fewer than 250,000 population.
Nonmetro counties:	
4	Urban population of 20,000 or more, adjacent to a metro area.
5	Urban population of 20,000 or more, not adjacent to a metro area.
6	Urban population of 2,500 to 19,999, adjacent to a metro area.
7	Urban population of 2,500 to 19,999, not adjacent to a metro area.
8	Completely rural or less than 2,500 urban population, adjacent to a metro area.
9	Completely rural or less than 2,500 urban population, not adjacent to a metro area.

Note: New Rural-Urban Continuum Codes based on the 2000 Census are not expected to be available until 2003. The development of the updated codes requires county-to-work commuting data from the long form of the 2000 Census and delineation of the new metropolitan area boundaries by the Office of Management and Budget. OMB's work is not scheduled to be completed until 2003. www.ers.usda.gov/briefing/rural/ruraltid1.asp

The **Renewable Energy Policy Project (REPP)** supports the advancement of renewable energy technology through policy research. We seek to define growth strategies for renewables that respond to competitive energy markets and environmental needs. Since its inception in 1995, REPP has investigated the relationship among policy, markets, and public demand in accelerating the deployment of renewable energy technologies, which include biomass, hydropower, geothermal, photovoltaic, solar thermal, wind, and renewable hydrogen. The organization offers a platform from which experts in the field can examine issues of medium- to long-term importance to policy makers, green energy entrepreneurs, and environmental advocates.

REPP receives generous support from the U.S. Department of Energy, the Energy Foundation, and the U.S. Environmental Protection Agency, the National Renewable Energy Laboratory (NREL), the Oak Foundation, the Sordna Foundation, and the Turner Foundation.

Abstract

Potentially adverse effects of windfarm visibility on property values can represent real costs to communities, yet few studies exist on the subject. The studies that are available are contradictory, and suffer from statistical flaws. A clearer understanding of actual effects of existing wind facilities will inform future decisions. To explore this subject this report analyzes 280 arms-length single-family residential sales using a hedonic regression model. The sales took place from 1996 to 2005 and are within 5 miles of a 20 turbines - 30 megawatt (MW) windfarm in Madison County, New York. The report differentiates itself from previous studies by visiting all homes ("ground truthing") in the sample to ascertain the actual level of turbine visibility. The analysis finds an absence of measurable effects of windfarm visibility on property transaction values. This result holds even when concentrating on homes within a mile of the facility and those that sold immediately following the announcement and construction of the windfarm in 2001. These results dispel the proposition that effects, either positive or negative, are universal. The report concludes by making recommendations to stakeholders and outlining possible considerations for further research.

Acknowledgements

I would like to thank my advisor Gautam Sethi for his patient and thoughtful feedback during the entire research and writing process. Additionally faculty members Mark Becker and Joanne Fox- Przeworski were extremely helpful. Kevin Orr and Priscilla Suits, and other members of the Madison County Tax and Assessors offices offered their advice and comments on countless occasions. Reviewers Ashok Gupta, Nathanael Greene, Charles Komanoff and Mark Thayer exhibited their candor, patience and thoughtfulness in their valuable analysis of the report. Haflan Eckholdt provided much needed late night statistical advice. My family volunteered as on call editors and sounding boards often. Lastly, without the unflappable and loving support of the most important person in my life, my wife, none of this would have been possible. Thanks to all of you.

I Executive Summary

With federal renewable energy tax credits and a number of state incentive packages in place (AWEA, 2005b), U.S. states are increasingly relying on wind energy to mitigate risks related to resource scarcity, increasing costs of fossil fuel extraction, greenhouse gas emissions and other environmental hazards (CRS, 2005). This shift has caused wind energy development to grow at an unprecedented rate. In 2005 new capacity totaling 2,400 megawatts (MW) was installed in the U.S., an increase of 35% over 2004 U.S. capacity (AWEA, 2006).¹ At the same time windmill sizes have become increasingly large in order to capture greater efficiencies per turbine, and the numbers of turbines installed per windfarm has increased to capture economies of scale (AWEA, 2005c). Litigious conflicts between community members and facility developers have occurred (Adams, 2005) and are likely to increase if the industry trends of increasing size and number continue. Community attitudes regarding wind energy are often promoted by small groups of organized opponents or proponents, therefore the sentiments of the entire community on average may be missed. One way to measure the community's disposition is to use property transaction prices (transaction values) as a proxy. If the visibility of a windfarm is believed by the members of the community to adversely affect the view from the home, the transaction value, with all else being equal, will be lower as compared to other homes without a view. Alternatively, if residents find the view acceptable, no change in property values will be discernable.

Many opinions exist on the effects of wind development on surrounding property values. For example, the two largest studies completed in the U.S. reach contradictory

¹ The American Wind Energy Association (AWEA) estimates that 2,400 MW of wind energy will supply energy for 600,000 homes (AWEA, 2006).

results. Haughton (2004) predicts sizable negative effects from windfarm development on property values in Cape Cod, Massachusetts while Sterzinger (2003) concludes from his analysis of 10 communities around the U.S. there are strong positive effects. Despite these contradictory results no studies to date have rigorously analyzed the subject by using a large sample of arms-length home transaction values combined with a verification to what degree each home in the sample can see the wind farm or not. Instead, with each new wind development interested parties are forced to rely on poorly constructed or inconclusive studies (Jordal-Jorgensen, 1996; Grover, 2002; Sterzinger *et al.*, 2003; Poletti, 2005), or comparisons to inappropriately analogous research (Zarem, 2005a). For instance in 2004, the Public Service Commission (PSC) of Wisconsin heard opposing conclusions of studies conducted by experienced economists (Poletti, 2005; Zarem, 2005b). Both cited, in their testimony, their frustration with the lack of available evidence in this subject area.

Compounding the lack of data problem, changes in property values are not likely to be taken into consideration by the developer and the community. These "hidden costs" or "externalities" are not weighed against the benefits of a project. Without proper analysis of these potential costs or externalities and a thorough understanding of when and how they affect property values, facilities may be either needlessly delayed or inappropriately approved. This report studies property values and windfarms with the hope of shedding light on these issues.

First the report reviews the existing literature on property values and windfarms finding in most cases a lack of rigor and insufficient detail to capture the complex relationship between home transaction prices and views, such as those found in research of high voltage transmission lines (HVTL) and property values (e.g. Des-Rosiers, 2002). Then

using data from a Madison County, New York community surrounding a 20 turbine windfarm, the report analyses home transaction values in an effort to ascertain if effects exist and to create a potential blueprint for future analysis of other communities. The data contains 280 arms-length single-family residential home sales which took place between 1996 and 2005; 140 occurred after facility construction began in 2001. None of the home sales were on properties that contained turbines, or received compensation from the operation of the turbines. Two methods of measuring the degree to which each home can see the turbines are developed, a simulated method and one involving field visits. Ultimately, as is discussed below, the method involving field visits was used for the regression model. The simulated method uses a geographical information system (GIS) model to predict visibility. Ten meter digital elevation model (DEM)² data provided by the United States Geological Survey (USGS) is combined with 10 meter ground-cover data by estimating heights of ground cover types and adding these heights to the surface elevations. The ESRI 3-D analyst viewshed algorithm, which is included in the Arc Map product, is used to analyze visibility. Then, GIS predictions are compared to field collected data. Although it incorporates techniques not previously used and reaches an accuracy rate of 85%, which is higher than the 50% accuracy rate found in the literature (Dean, 1997; Maloy and Dean, 2001), it is deemed an unsatisfactory level of accuracy for this report's hedonic analysis which requires greater than 95% accuracy. Therefore, the second, field visit method is used.

² The DEM is a digital representation of the elevation of locations on the land surface. A DEM is often used in reference to a set of elevation values representing the elevations at points in a rectangular grid on the earth's surface.

For this method, each home in the sample is visited and the degree to which each of these homes can see the windfarm is quantified using a scoring method which attempts to minimize bias. From each home each of the twenty turbines is given a 0 (no view) to 3 (full view) score, which are then totaled resulting in a 0 to 60 score specific to that property.³

Figure 1: Turbine Visibility Scoring Method

As well, a GIS is used to quantify the exact distance from each home to the nearest turbine. These two characteristics, view of and distance from turbines, are combined with a number of house and neighborhood characteristics. The combination of characteristics is then used in a hedonic regression model to investigate the marginal effect that the view of and distance from turbines has on home sale prices. The hedonic pricing model is well established in its usefulness in investigating the effects environmental characteristics have on home values (e.g. Dale *et al.*, 1999).

The report finds that the model significantly predicts home values (*t*-value 49.56, *p*-value 0.000, R^2 0.792), and on average that there are no measurable effects on property values based on the view of and distance from turbine characteristics (*p*-value 0.410 and

³ The actual range of scores for the sample set used in this report is 0 to 43.

0.679 respectively). This finding holds both temporally and spatially. In other words, homes which sold in the year the project was announced and constructed (2001), and had a clear view of the turbines, are not affected uniquely (p-value 0.742); and no measurable effect is found for homes located within a mile of the facility (p-value 0.656)⁴.

Additional tests are run to see if the township of Fenner in which the turbines are located, and to which payments are made by the facility owner, is accordingly perceived to have a positive value in the eyes of home purchasers as compared to the other townships. If the payment to the township is considered to be a distinct advantage by home purchasers, by adding needed dollars to the town budget, for example, it might be found the homes in Fenner are priced at a premium to other townships, all else being equal. In our analysis no measurable premium is found (p-value 0.689).

These results are important to policy makers and other stakeholders because they dispel the supposition that windfarm development has universally negative effects on home values. They support the results previously collected via surveys which find that a majority of residents in communities surrounding other wind facilities not only perceive the turbines to be "acceptable" (Warren *et al.*, 2005), but also "relatively nonexistent," by rarely (< 3.0%) spontaneously mentioning them in descriptions of their surroundings (Braunholtz and MORI-Scotland, 2003).

⁴ A p-value is a measure of statistical significance, which can be reported in a number of ways in studies (e.g. margin of error, probability, or significance). They all report the same thing, the degree of confidence that the results were not reached by simple chance. As sample sizes grow, and variation among them becomes more predictable, more confidence can be had that "statistically significant" results from the analysis of the sample set can be transferred to the entire population. Conversely, if sample sizes are small, and variation among them is less predictable, results can not be validated against an average, and therefore present difficulties in being extrapolated to the population. In these cases results should be taken anecdotally or should not be transferred outside of the sample set.

With a paucity of research on the subject of effects of wind facilities on property values and a great deal of speculation regarding the actual effects, policy makers are forced to rely on poorly constructed studies and opinions. This report attempts to move the discussion toward the facts. Its research finds that in this community of 280 homes no effect is found. To the degree that these results are corroborated by further analytical research in other communities, the issue of negative impacts of windfarms on property values might take a lower priority in the decision making process. This report makes policy recommendations to stakeholders based on the results of this study and outlines possible areas for consideration which should be explored in future research.

2 Introduction

With federal renewable energy tax credits and a number of state incentive packages in place (AWEA, 2005b), the States are increasingly relying on wind energy to mitigate risks related to resource scarcity, increasing costs of fossil fuel extraction, green house gas emissions and other environmental hazards (CRS, 2005). Because wind energy, "is one of the lowest-priced renewable energy technologies available today" (USDOE, 2005, p. 1) and its resources are well distributed around the country, it has enjoyed an average annual growth of almost 20% over the last decade (GWEC, 2005) and is expected to continue its growth into the future (EIA, 2006). In the United States, twenty-one states have implemented a Renewable Portfolio Standard (RPS) which requires a percentage of retail sales to be from renewable sources (AWEA, 2005b). The American Wind Energy Association (AWEA) forecasts a 7-fold increase in the use of wind energy in the U.S. by 2020 (AWEA, 2005e). In 2005 alone roughly 2,400 MW (or 1666 turbines⁵ in 140 "windfarms"⁶) have come online in the U.S. (AWEA, 2006).

Not only have the amount of windfarms been increasing but the number of turbines in each development has increased to capitalize on economies of scale. Additionally the sizes of the structures over the last 20 years have changed dramatically in order to increase turbine efficiency. As the height and rotor diameter of turbines increase, the power generated from the turbines grows exponentially (AWEA, 2005c). In 1980 when the Altamont Pass wind facility was erected outside of San Francisco in California (CA),

⁵ Estimated by using an average turbine size of 1.5 MW and farm size of 100 MW. Using this same estimate, if New York State is to meet its RPS goals of 25% by 2013 (NYS DPS, 2004) 30 new windfarms will have to be sited.

⁶ These wind energy production facilities usually contain groupings of 10 or more turbines referred to as a "windfarm," because they are laid out, "as a farmer might approach . . . a field" (Gipe, 2002).

turbines averaged 30 meters in height (Pasqualetti, 2002). Now land based turbines sit on towers as high as 90 meters, and have blade lengths of 45 meters (AWEA, 2005c) totaling 135 meters (442 feet) from base to tip.⁷ While increasing efficiency, this difference in heights makes them considerably more visible from long distances.

With the high number of windfarm installations expected to occur in the U.S. to meet RPS goals over the next decade and the ever increasing size of the facilities and the turbines themselves, it is inevitable that there will increasingly be conflicts between developers and members of the communities in which the windfarms are sited. Often these clashes revolve around environmental "aesthetics," or how well the turbines fit into the surrounding environment in the eyes of community members. Findings suggest that respondents prefer smaller turbines over larger ones (e.g. Wolsink, 1989; SFI, 2003) and fewer structures rather than more in each group (e.g. Devine-Wright, 2004). Accordingly, homeowners have often claimed a proposed wind facility will ruin or "harm their view" (e.g. AP, 2006).

How can this claim be tested? When property owners say windmills will "ruin" their view, they are claiming both that there is some intrinsic value of "vista" (or view)⁸ from their home, and that if the proposed windmills can be seen from the home this value will be diminished. It follows that if you can analyze home sales that have visual contact with the windmills in comparison with ones that do not, all other things being equal, an average effect can be verified. In other words, community attitudes of a wind development

⁷ Offshore turbines can be even bigger ranging up to 165 meters from base to tip.

⁸ For this report, a distinction is made between "vista" and view or viewshed. "Vista" will always refer to the value of a home that is derived from a "good view" from the property. "View" or "Viewshed" will refer to the degree to which a property can see the windmills. In other words, "A property not only had a beautiful vista, but had a view of the windmills too."

can be translated into home values, just as, for instance, the perceptions of a safe neighborhood or good quality public schools are translated into sale prices. This correlation of community attitude and property values has been confirmed in studies of other environmental attributes such as open space (e.g. Irwin, 2002), high voltage transmission lines (HVTL) (e.g. Des-Rosiers, 2002) and environmental stigmas (e.g. Dale *et al.*, 1999).

What are the ramifications to the community or society of such potential connections? If the effect of visibility of wind facilities on property values is universally highly negative, these costs might be very high. Haughton (2004), in his study of the proposed Cape Cod windfarm forecasts depreciation of property values in the billions! Yet, often changes in home values are outside the normal transactions of a developer and a community and are thus "hidden costs" or "externalities" of a project. These externalities are often grouped together and termed "environmental impacts" (EMC, 2005). Windfarm developers are often required, depending on the state or local laws, to investigate the nature and magnitude of these externalities by preparing an environmental impact statement (EIS) or something similar⁹ often modeled after the Federal requirements as directed by the National Environmental Policy Act (NEPA)¹⁰ regulations. An EIS is a report describing the investigations conducted by the developer of potential effects the facility will have on the surrounding environment. The report has a number of functions. First, it allows interested parties and stakeholders an opportunity to peel back, investigate and in some cases challenge the development's declared environmental impacts. Secondly, it provides a record that can be later challenged if assertions are found to be incorrect. Lastly, it provides

⁹ More often than not, local laws will permit development to take place without a full environmental review (GAO, 2005), but often some type of impact assessment is required

¹⁰ National Environmental Policy Act (42 U.S.C. & 4321)

a schedule of expected environmental costs that can be compared against the proposed benefits any project will provide. In order for a project to proceed, "it must be demonstrated that the need for the proposal outweighs all adverse impacts" (EMC, 2005, p. 10).

Because of the importance of understanding actual effects on property values as costs to be weighed against benefits, it may be expected that this issue has been widely studied. However, this is not the case. Some studies exist using actual real estate transaction prices, but have made critical errors which weaken the results (e.g. Storzinger *et al.*, 2003; Poletti, 2005), as explained in section 3. In the absence of actual prices, studies have used surveys of real estate professionals and homeowners as a proxy (e.g. Jordal-Jorgensen, 1996; Grover, 2002; Haughton *et al.*, 2004). Yet none of these studies reported their results accompanied by levels of significance.¹¹ Accordingly decision makers are forced to make educated guesses as to the predicted effects of a proposed windfarm. One controversy was played out in Wisconsin as two experts argued over the potential effects of the proposed Forward Wind Facility (Zaremb, 2005b) and (Poletti, 2005) with each reaching distinctly different conclusions. Without well-designed studies with solid conclusions to work with, planners, developers, and potentially impacted communities will continue to needlessly delay or inappropriately rule on projects that might otherwise be decided differently.

This report examines whether property values were affected by a windfarm installed in Madison County in 2001. 280 home sales, which took place between three quarters and

¹¹ Refer to discussion of "significance" in footnote 4 on page vii.

five miles of a 20 turbine windfarm, are analyzed using a **hedonic pricing model**¹² to establish the degree of impact that a view of windmills might have had on the transaction values of these homes. The report first outlines previous studies on the subject. Next the report presents methodology and results. Lastly the report discusses conclusions and makes policy recommendations to interested parties and research recommendations concerning decisions on siting wind facilities.

¹² A hedonic pricing model, as discussed in section 5.1, is a statistical device which allows market goods to be broken into their component characteristics. It is often used to value individual characteristics of cars, such as the value of a sunroof, and homes, such as the value of a pool.

3 Overview of Previous Studies

The literature on wind energy facilities and surrounding property values can be grouped into three categories of increasing order of relevance for our research: survey-based studies (Jordal-Jorgensen, 1996; Grover, 2002; Haughton *et al.*, 2004; Khatri, 2004), transaction-based studies of analogous high voltage transmission lines (HVTL) structures (e.g. Delaney and Timmons, 1992; Hamilton and Schwann, 1995; Des-Rosiers, 2002), and transaction-based studies of windfarms (Sterzinger *et al.*, 2003; Poletti, 2005).

3.1 Survey based studies

When transaction data are not available either because a windfarm has only been proposed or data are not recorded or available for public use,¹³ surveys can be used to estimate values of viewshed impacts. Surveys specifically asking questions regarding values can be directed at assessors and real estate agents who have professional knowledge of how values can be impacted by a change in the surrounding environment (Grover, 2002; Haughton *et al.*, 2004; Khatri, 2004) or to residents who can offer their value judgments (Jordal-Jorgensen, 1996; Haughton *et al.*, 2004). Both of these methods can suffer from inflated and unrealistic values (Kroll and Priestley, 1991), and therefore it would be inappropriate to use these values as a replacement for actual economic impacts, as is discussed below. In the absence of other data, and if the surveys are taken using random and unbiased methods, they can be illustrative of community attitudes and indicate areas for further study.

Jordal-Jorgenson (1997) conducts two types of surveys using contingent evaluation methods. Contingent evaluation methods attempt to establish in monetary terms “non-

¹³ In the U.K., for example, residential transactional values are not public information.

market” environmental values by asking people how much they are willing to pay for an environmental amenity or to have an environmental nuisance removed.¹⁴ Jordal-Jorgenson surveys 342 homeowners living “near” windmills in Denmark, inquiring if they find the turbines a nuisance and, if so, what they would be willing to pay to have them removed. 13% of the homeowners find them a nuisance and are willing to pay \$140 per household per year on average to have them removed.¹⁵ Additionally, Jordal-Jorgensen asks respondents what they would be willing to pay to not live near the windmills. The study finds that people are willing to pay between \$2,314 and \$13,429 dollars to not live “near” a single or a group of turbines respectively.¹⁶ The term “near” is not defined. The study points out that because the result is an average, a wide variety of impacts could be found among the homes, with individual homes experiencing potentially large impacts. Additionally, the author admits that the small number of houses, 26 out of 342, available for analysis near the turbines did not provide a statistically significant result, and that therefore the results could be “due to coincidental factors” (p. 2).¹⁷ This is a problem, as well, with a number of other studies outlined below. Without a reported level of confidence in the results, readers are recommended to use the findings anecdotally.

Similarly, Grover's (2002) survey results of 13 county tax assessors around Kittitas County, Oregon should also be used anecdotally because he both uses a very small sample size, and implies causality where only correlation has been found. Of the 13 county assessors that are interviewed, 6 state that their county's residential properties have views of

¹⁴ Surveyors use various techniques to improve the predictive power of this method. For further reading on this subject, Bateman (2002) is a good resource.

¹⁵ Converted from Dutch Kroners (DKK) using 1996 exchange rates

¹⁶ Converted from Dutch Kroners (DKK) using 1996 exchange rates

¹⁷ Refer to footnote 4, on page vii, for a brief discussion on statistical significance, and how results which are reported without measures of significance should be used anecdotally and not empirically.

turbines, and 5 out of 6 report no complaints from residents. The report declares, "There is no evidence indicating that views of wind turbines decreased property values." (p. 4). Technically this is true, but with only 6 assessors reporting it is not possible to have a great deal of confidence in the results. Additionally, the fact that residents did not complain (correlation) does not mean conclusively that property values are not affected (causation). It is possible other reasons intervened, such as either ignorance of residents that a reduction in assessed values could be requested, that the process would be futile, or perceptions that evidence warranting a decrease would be difficult to collect on their own.¹⁵

Although previous studies leave much room for criticism, the work by Haughton *et al.* (2004) is more solid because it largely uses accepted rigorous techniques of sampling and survey construction. Yet, predicting actual effects on property values based on these results would be risky because the results are descriptive,¹⁶ not analytic, no significance values are reported, and survey responses might be influenced by other variables. Despite these limitations the results are illustrative of a community searching for solid answers to questions of property value impacts. As part of an economic analysis of the proposed offshore windfarm in Nantucket Sound, Haughton *et al.* (2004) conducts a survey of 546 real estate agents ($n=45$) and residents ($n=501$). It is the first large scale survey concerning wind energy in the U.S. since the late 1980s (Pasqualetti and Butler, 1987; Thayer and Freeman, 1987; Thayer and Hansen, 1988). The report concludes that there is an adverse expectation about the proposed windfarm on property values from both residents (21%) and realtors (49%). Homeowners believe that average values will decrease by 4.0% with losses

¹⁵ Grover (2002, p.5) states that in Lincoln WI, the assessor asked a complaining resident to show that nearby properties had diminished in value. This most likely is outside the abilities of the average homeowner.

¹⁶ Descriptive results describe the distribution of variables without regard for causal or other hypothesis. Analytic studies are designed to examine these associations. (Last, 1995)

of 10.9% expected for waterfront properties. Realtors expect losses to total 4.6% on average. To extrapolate from these results is risky though. In a comparison of survey and hedonic approaches Brookshire *et al.* (1982) caution that, "biases due to lack of experience must be considered" (p. 176). The responder's estimates for anticipated impacts might be higher than those actually experienced. For example, the results of a survey in Scotland of 1,810 adults living near 10 windfarms with 9 or more turbines (Braunholtz and MORI-Scotland, 2003, p. 10) found that:

"Of those that lived in their homes prior to the construction, concerns about specific problems that might arise as a result of the windfarm do not seem to have materialized in many cases...Furthermore, while around half (54%) anticipated no problems over a range of issues associated with the windfarm development, as many as eight in ten (82%) say that there actually have been no problems."

This is corroborated by Warren (2005), in a study of residents surrounding windfarms in South-West Ireland who stated, "73% of residents across all [spatial] zones feel that their fears have not been realized" (p. 864). Finally, the predicted amount of value degradation as reported by Haughton *et al.* could be confounded by other variables, such as whether the respondent's home has a view of the sound, if they believe wind energy to be necessary, to what degree they believe it might contribute to positive environmental change, or if they had seen an actual windfarm. Yet Haughton does not report these interactions between these variables.

Despite these weaknesses, their results are important in other ways. They illuminate a belief that the brunt of the effects will be felt by residents on the water in full view of the sound. Haughton found that 69% of realtor respondents believed the effects of the windfarm would be felt to a greater extent on ocean front houses, with only 2% expecting the effects to be distributed evenly (29% no opinion). The reasoning for this follows the

logic that the "vista" of the sound provide value to the houses (e.g. Rodriguez and Simans, 1994; Seiler *et al.*, 2001). Incorporated with the belief that the addition of windmills will decrease the beauty of that "vista," it follows that the values of these homes will be diminished. Further, it might be the case that *ceteris paribus*, home values more dependent on "vista" will experience an effect where others will not. There might be some threshold where an effect begins such as that found with HVTL in Des-Rosiers (2002) study where he found effects (positive and negative!) completely disappear outside of 500 feet from the transmission line. All told, it would be difficult to entirely dismiss the results of Houghton *et al.* as the musings of the inexperienced or the hysterias of those in fear. The proposed windfarm will consist of 130 turbines, and as mentioned above, people have a preference for smaller windfarms over larger ones (Wolsink, 1989; SEI, 2003). It seems likely that house values in that region will react in concert to some degree with resident dislike; the question will be in what amount.

The results of Khatri's (2004) survey, for reasons similar to Houghton (2004) are illustrative of perceptions rather than actual values. Khatri mailed 1,942 surveys to licensed surveyors in Great Britain (U.K.); 405 voluntarily responded, and roughly 80 were surveyors who had experience with residential transactions near windfarms. The report finds that a majority (60%) of surveyors reported that property values will be adversely affected, though closer inspection finds dilutions to the results in three ways. The experienced respondents were concentrated in Wales and Scotland, where 43% of U.K. wind projects are located,²⁰ yet the percentage of Welsh (45%) and Scottish (55%)

²⁰ from www.bwza.org as cited by Khatri (2004)

respondents reporting decreased values is below the survey's national average (60%).²¹ This implies that the national average is not appropriate to use as a final result. Secondly, because responses were voluntary, there might be a selection bias as the sample was unlikely to represent the population (Heckman, 1979).²² Lastly the actual survey is not provided so it is difficult to assess the quality of the research, for example the nature of the questions.²³

3.1.1 Conclusions drawn from survey studies

The survey studies do not give a clear indication as to whether there is an actual decrease in value. Even Haughton's (2002) study suffers from the likelihood that without actually experiencing what windmills look like in Nantucket Sound, respondents will overestimate the impacts. Haughton does elucidate, though, the possibility of thresholds of sensitivity for price devaluation. The results of these studies reinforce the need for more research and lead us into the next category of studies that are often used as a proxy for windfarm property value analysis: transaction-based studies of analogous HVTL structures.

3.2 *Transaction based studies of analogous HVTL structures*

With little to go on from existing research of wind energy and property values, interested parties have turned to property value studies of high voltage transmission lines (HVTL) in an attempt to make a benefits transfer from these structures to windfarms. It has been found that HVTL structures are perceived negatively and often adversely affect property values

²¹ A decrease in experienced effects is more recently corroborated by Warren (2005, p.853) "inverse NIMBYism"

²² It is possible that only those that were bothered by the wind farms responded because they cared the most. If that is the case, then the results are skewed and in actuality less assessors feel there will be a decrease in property values.

²³ The report results "60% agreeing" imply that a leading question was used such as, "Do you agree the windfarms hurt property values?"

(e.g. Kroll and Priestley, 1991; Des-Rosiers, 2002). Because newer windmills are larger, and often more noticeable because of moving parts than HVTL, the temptation is there to assume turbines will have an equal or greater effect on property values (e.g. Zarem, 2005a).

3.2.1 Are HVTL structures and windmills viewed similarly?

Research conducted in 2003 in Ireland, based on a survey of 1,200 people indicated that windfarms were preferred over HVTL towers (as well as cellular towers and fossil fuel stations) (SEI, 2003). Why is this? Thayer and Hansen (1988) found that perceptions of windfarms were based on symbolic aspects in addition to aesthetic ones. Devine-Wright (2004) concurs, stating that symbolic aspects “could include the degree to which turbines are associated with wider environmental concerns such as climate change and feelings of personal responsibility to address such problems” (p. 129). This more complicated view of turbines is echoed in Warren (2005). When respondents living around windfarms were asked to rank the most positive and most negative aspects of the turbines, their presence in the landscape topped both categories (34% and 44% respectively). People either love them or loathe them.²⁴ It follows that if the U.S. effort in building windfarms is increasingly perceived as a reduction of risks, and therefore a solution to problems of energy scarcity and security, reaction to them will improve. Conversely, it is unlikely that HVTL would ever be perceived as offering a greater good. In fact, however unfounded,²⁵ electromagnetic radiation from HVTL is still a concern for individuals.²⁶ Because of these differences in

²⁴ This turn of phrase has been used often to describe public sentiment (e.g. Bishop and Proctor, 1994; Freris, 1998).

²⁵ Goeters (1997) reports that no study has provided scientific evidence of a relationship between cancer and HVTL proximity.

²⁶ Delaney (1992) reports that, “Even appraisers who had not appraised such property [near HVTL] believe that power lines contribute negatively to property values [for health reasons].” (p. 315).

perception between windmills and HVTL it would be imprudent to make a one for one comparison between the two.

3.2.2 Arc spatial property value effects of HVTL similar to windfarms?

Des-Rosiers (2002) found that effects from HVTL and their accompanying easements²⁷ disappeared outside of 500 ft. Additionally his results show a very sensitive interplay between proximity to the tower structure and proximity to the easement. Des-Rosiers (2002) found both an unambiguous negative effect due to towers and an unambiguous positive effect due to easement of HVTL on house values. In his review of the HVTL literature Des Rosier's (2002) finds that most studies conclude that, "Other physical as well as neighborhood attributes prevail [over proximity to HVTL] in the price determination process." (p. 277). This conclusion is also borne out in his findings that the negative effects of a view of a tower from a house immediately adjacent to it are overwhelmed by the positive effects of living near a HVTL easement just a few doors away (Figure 1).

If HVTL and windmills exhibit similar effects on values, can it be assumed that property value effects of windmills will entirely disappear outside of 500 ft? Perhaps they will disappear, but at what point: one tenth of one mile, a half of one mile, or some other distance? Additionally, what effect will some overriding positive attribute, such as "vista" of sunsets, a bucolic field, or a mountain range, have on the potentially adverse effects of a view of windmills in close proximity?

²⁷ In the case of HVTL easements are clearings through which transmission lines pass. They have benefits, for example, in that ensure a development free zone and can provide access to green space.

Figure II: Property Value Effects of HVTL and Distance

Source: (Des-Rosiers, 2002, p.293) Effects on houses adjacent to towers (FACNGPYL), are negative (-9.60%). Those on lots 1 or 2 away (1LOTPLY & 2LOTPLY) are positive (11.60% and 8.70 % respectively).

Lastly, it is interesting to consider Warren's (2005) theory "inverse-NIMBYism" that there is an increased appreciation for wind turbines as you move closer to them, and the findings of Braunholtz (2003) which show largely ambivalent and positive reactions of residents to nearby turbines. Braunholtz finds that of the people living within 5 km (3 miles) of turbines 45% had largely positive views (with 6% having negative views and 49% ambivalent/no opinion), which differed significantly from those residents living outside of 10 km (6 miles) of which 17% had positive views (with 6% negative and 77% ambivalent/no opinion). The logical extension of inverse-NIMBYism on property values would have values increasing as distance from turbines decreases! Despite this possibility the report assumes the conventional stance that windmills will either decrease values or not change them at all.

3.2.3 Are temporal property value effects of HVTL similar to windfarms?

Kroll (1991) finds that where newly installed HVTL have effects on property values, they tend to fade away entirely over four to ten years. This is similar to results of some studies conducted near wind energy facilities. Exeter-Enterprises-Ltd (1993) found via its longitudinal study of facilities in the U.K. that negative perceptions diminish over time. "The results show that any change of attitude... is toward thinking that wind power is better." (p. 53) On the other hand, Devine-Wright (2004) believes the opposite. His re-analysis of Krohn's (1999) results show that negative perceptions of development can increase over time. Is this because older turbines are often decommissioned yet are not removed? Thayer (1988) believes so, finding that community sentiment is correlated with the number of turbines in operation, and if turbines are standing idle, negative perceptions increase. Given these contradictory results, a generalization of the similarities of HVTL and windfarm's temporal effects is not appropriate.

3.2.4 Conclusions drawn from analogous HVTL studies

The comparisons of HVTL effects on property values and those of windmills seem unclear. HVTL structures are not viewed the same as windmills, and windmills can even take on positive connotations. Moreover the interplay between HVTL and property values is both tenuous and very sensitive to distance and other neighborhood characteristics. There are spatial and temporal thresholds for HVTL property value effects which also could exist for windmills. As with the survey study analysis above, a careful look at HVTL studies reinforce the need for more research. Possibly other structures, for instance offshore drilling platforms, could be used as a more appropriate proxy as will be discussed further in the recommendations section. The studies conducted using actual property transaction

values surrounding wind facilities offer more empirical data, but are also inconclusive as to the effects of windfarms on these values.

3.3 *Transaction based studies of windmills*

To date only two studies have been conducted using actual transaction values of homes surrounding wind facilities. The results of these are varied. Sterzinger *et al.*, (2003) conclude that property values rise in the area of windfarms, and Poletti (2005) comes to the conclusion that no effect exists.

Sterzinger *et al.*, (2003) analyses roughly 24,000 transactions near 11 windfarms in the U.S., and compared average transaction values for houses in a control area outside the viewshed of the windfarm with transactions occurring within the viewshed (a 5-mile radius). The study comes to the conclusion that, "There is no support for the claim that wind development will harm property values." (p. 9), and even declares, "For the great majority of projects [windfarms] the property values rose more quickly in the viewshed than they did in the comparable community." (p. 2). Although this study is often quoted,²⁸ its methods have been criticized (e.g. ECW, 2004) for four reasons. First, the authors attempt to calculate a value for the variable "view of windmills," without properly controlling for it. There is no attempt to discern which properties within the ten different 5-mile viewsheds can see the windfarm or not. In effect, the study makes the erroneous assumption that all properties in the 5-mile radii can see the windfarm, when many houses' views in fact are obstructed by geological features, trees, and other houses (RBA, 1998a; Poletti, 2005).²⁹

²⁸ A "Google" internet search using all of the following words, "RLPP", "wind" and "property" generates 18,600 results [tested 2-20-06]

²⁹ Sterzinger *et al* analyze the community surrounding the Madison County windfarm, which is the subject of this report. We found 66% of the homes sampled in the 5 mile radius could not see the windfarm at all.

Secondly, the analysis does not control for distance to the turbines, thereby making the assumption that the "viewshed" effect is the same, on average, for homes five miles from the windfarm and those in immediate proximity to the turbines. Third, there are problems with how the study validates its results. The report provides readers with only R^2 (or goodness-of-fit) values for its outcomes, and this is problematic, since, by itself, the R^2 statistic is a poor indicator of explanatory power (Halcoussis, 2005). Compounding this problem, the report gives R^2 values which are very low, for instance 0.02 for some models, which is saying in essence the model describes only 2% of the actual movement of property values. Despite this somewhat flagrant disregard for rigor it treats these models as it does models where the statistic is high, for example 0.85. This inconsistency is not addressed by the report. The last reason this research is often criticized is that no attempt is made to sort out inappropriate transactions. Sales that are not arms-length (divorce, sales between family members, estate sales etc.) are included. By doing so the report includes transactions that do not represent the agreement between a willing buyer and a willing seller, a requirement for accurate analysis. Combined, these four omissions in rigor render the results of the report extremely weak, if not entirely misleading.

The analysis by Poletti (2005) improves on that of Sterzinger *et al.* (2003) by culling out transactions that were not arms-length. As well, it excludes sales of homes built before 1960, in an effort to control for house-specific characteristics such as construction quality, amenities and condition. Poletti looks at roughly 300 sales that occurred in and around two windfarms in Wisconsin and Illinois. He comes to the conclusion that there is not sufficient evidence in the data to warrant rejection of the claim that windfarms have an effect on property values. Poletti compares average values of properties surrounding the windfarms,

which he entitles “target area” with those in a “control area,” which is outside the view of the windfarm. However, Poletti does not attempt to measure to what degree, if any, homes can see the windfarm. The author describes the area surrounding the windfarms as rolling with potentially obscuring features, so the implication is that some of the properties have no view of the windfarm. Further, no effort is made to control for distance. Although statistically sound techniques were used to compare the control area to the target area, by not properly controlling for view and distance, the study results are inconclusive at predicting the effects of the windfarm on property values.

3.3.1 Conclusions drawn from transaction studies

Taken together, the two studies using transaction values still leave open to conjecture the question as to the actual effects of windfarms on property values. By not appropriately sorting out misleading data, empirically establishing the degree to which houses could see the windfarm, and not factoring in distance, these studies most likely miss the potentially subtle interaction between view and value that has been found with other environmental stigmas (Des-Rosiers, 2002).

If results of studies of property values and windfarms can be confidently applied in windfarm siting decision making, the above analysis makes clear the importance of using large samples (>30), of measuring the actual visibility of and distance from turbines from each house, and of testing the results for significance. The following analysis attempts to do this. First there will be a brief discussion of the study area, then methodology, results, conclusions and recommendations.

4 Study Area

The Fenner windfarm was announced near the end of 2000; construction commenced in the spring of 2001 and was completed in the fall of 2001 (Moore, 2005). The 30 megawatt (MW) installation consists of 20 turbines, each 328 feet tall, with a rotor radius of 110 feet, making the top of the turbine blade's sweep roughly 440 feet above the ground. The windfarm sits atop 14 different parcels over 2,000 rolling acres. The Fenner Township receives \$150,000 as a payment in lieu of taxes (PILOT) from the project owner which goes to increased road maintenance and schools (Cary, 2005). As is required under the New York State Environmental Quality Review Act (SEQRA) an Environmental Assessment Form (EAF) was prepared and submitted to the lead agency which was the Town of Fenner Board. It issued a Negative Declaration on the project based on the EAF, citing adverse impacts as insignificant. The public was given a number of opportunities to participate in the decision making process at town board and planning board meetings, which were characterized as both numerous and without much opposition (Moore, 2005). Larger maps of the study area are included in Appendix B.

Figure III: Fenner Turbines & Parcels

Source: Madison County Tax Office

(Large dots are windmills, rectangles are parcels, parallel lines are HVTL, and the dark lines are roads.)

5 Methodology

The general purpose of this case study is to test if the view of the Fenner windfarm from homes inside of 5 miles from the windfarm has any significant effect on transaction values. "View" is defined using a continuous variable from 0 (no view) to 60 (a full view of all 20 turbines). The study additionally investigates how this effect varies with distance (spatially), time (temporally) and house value. Lastly, the effect and degree of the PILOT payment to Fenner Township is investigated.

The hedonic pricing model is well suited to dissect these issues revolving around windfarm acceptance. The rigor of the instrument in measuring the marginal contribution housing and neighborhood characteristics have on home transaction values is well supported in the literature for assessment purposes (Brookshire *et al.*, 1982; Malpezzi, 2002; Sirmans, G.S. *et al.*, 2005a; Sirmans, G. Stacy *et al.*, 2005b), in establishing effects of HVIL (Kroll and Priestley, 1991; Delaney and Timmons, 1992; Hamilton and Schwann, 1995; Des-Rosiers, 2002), in valuing the contribution "vista" has to value (Rodriguez and Sirmans, 1994; Benson *et al.*, 2000; Seiler *et al.*, 2001; Bond *et al.*, 2002), and in determining the effect of open space (Irwin, 2002) and environmental stigmas (Dale *et al.*, 1999). The model, given enough data, is sensitive enough to allow sales to be grouped temporally (e.g. by year), spatially (e.g. by distance from an amenity such as a body of water), and economically (by the value of the home). Once these divisions are made, variables of interest (e.g. the marginal contribution of fireplaces to homes values) from one group can be compared to other groups, both in terms of significance and the level of contribution.

5.1 *The non-linear hedonic model*

The non-linear hedonic pricing model in its present form is often attributed to Sherwin Rosen (1974) for his contribution to its utility in deciphering housing prices. A number of reviews (Malpezzi, 2002; Simans, G. Stacy *et al.*, 2005b) validate his construction in its ability to rigorously predict changes in residential transaction values based upon characteristics of the homes.

The model takes the form:

$$\text{Log (Sale_Price)} = f(\text{Physical Characteristics, Other Factors}).$$

“Physical Characteristics” often used include square footage of the home, lot size, number of bathrooms, number of bedrooms, type of construction, etc. “Other Factors” often include proximity to amenities, school district, local tax rates, and in this case study, “view” of and distance from turbines.

5.2 *Variable selection*

Although inclusion of the most commonly significant variables as taken from the literature (e.g. Simans, G. Stacy *et al.*, 2005b) is important and necessary, often local conditions can direct the proper construction of the model more than convention. Local assessors, realtors, and residents often have considerable insight into how prices are affected by changes in characteristics and other factors. Therefore in constructing the model used for this report Siman’s (2005b) recommendations for variables were included as well as those cited by a survey of two local assessors and two real estate agents. The results of the two inquiries are listed in Table I and Table II.

Sirman's list included all of the variables on the local expert list except School District, the distinction between distance to I90 and distance to State Route 20, local tax rates and building styles. All of the available variables from both the Sirman list and the local expert list were included.

Table 1: Sixteen Most Significant Hedonic Variables in Housing Studies

Variable	Appearances	# Times Positive	# Times Negative	% Time Significant
Square Feet (SFT A)	69	62	4	90%
Central Air	37	34	1	95%
Age at Time of Sale	78	7	63	90%
Pool	31	27	0	87%

5.3 Data collection

The data concerning transaction values and assessor information is collected from Madison County Real Property Tax Office. From January 1, 1996 through June 1, 2005, 452 sales took place that were coded "arms-length" transactions by county assessors, and were within 5 miles of the windfarm. Of these, 152 were removed as land-only sales³⁰, and upon closer inspection 20 sales (15 land-only and 5 non arms-length) were found to have been coded incorrectly and were removed. For the remaining 280 sales, assessor records from the

³⁰ "Land Only" sales refer to sales of parcels that did not contain a house at the time of sale.

closest preceding inspection were collected providing information about structural characteristics and location.

Although most of the recommended variables were included in the Madison County records, there were many gaps in the records for the following variables which made them unusable: Pool, deck, number of stories, number of rooms, and garage spaces.³¹ Data for time on the market was not available, and therefore was not included.³²

Table II: Twelve Most Influential Characteristics Recommended by Local Experts

Variable	Percent of the 4 Local Experts Recommending this Variable
# of Full Baths	100%
# of Bedrooms	100%
Overall Condition	100%
Basement Type	75%
# of Fireplace	75%
Acres	75%
Square Feet (SFLA)	75%
Age at Time of Sale	75%
Building Style	50%
Distance to I90	50%
School District & Taxes	50%
Distance to State Route 20	50%

Sale price was adjusted to 1995 dollars by using the Department of Labor's CPI for Rural New York (SALE_PRICE_95) and then converted to its natural log

³¹ During field analysis decks and pools were rarely present, and the number of rooms and stories was expected to be highly correlated with the square feet, so their exclusion was not expected to compromise the results. The County is conducting a reassessment of every house in its records, which should be completed in 2006, which is expected to fill in the gaps of these characteristics.

³² Although time on the market generally has the effect of lowering the price it has in some cases produced higher prices. It is assumed that this is because buyers can wait for the price that they want, or that the market slowly appreciates up to their asking price (Simmons, G. Stacy *et al.*, 2005b).

(LNSALE_PRICE_95).³³ The thoroughness of this adjustment was tested by including a continuous variable (DEED_YEAR) to account for a potential linear escalation in market price which exceeded the CPI inflation rate. Four binary variables (WINTER_SALE, SPRING_SALE, SUMMER_SALE, and FALL_SALE) were included in the model to account for seasonality in the housing market. Descriptive statistics for all non-viewshed variables are given in Appendix A: Tables IX and X.

A geographic information system (GIS) was used to calculate distance from the houses to the nearest turbine (DIS_TO_MILLS). Elevation and spatial location layers were populated using the 10 meter digital elevation model (DEM) provided by the United States Geological Survey (USGS), ortho-imagery was provided by New York's Department of Environmental Conservation (NYDEC), and roads, windmill locations and parcels were provided by the Madison County Planning Department. Parcel shapefiles did not contain actual house location, so a housepoint file was constructed using the ortho images overlaid with the parcel map, for each parcel that sold during the study period.

All layers were projected using the NAD 1983 Coordinate System and the New York State Plane Central projection. Where possible, shapefiles were corroborated with ortho-images, as was the case with the windmills, to ensure locational accuracy. Distances to major roadways (Route 20: DIS_TO_RT20 and U.S. Route 90: DIS_TO_I90) were calculated using linear distance. Although this is not a measurement of actual driving time

³³ To account for the "bubble" in the housing market binary variables for all years were tested but were found to be insignificant, so the CPI 1995 adjusted prices were used without these variables.

to these arteries, field experience indicated that the high density of roads in this area allowed residents a fairly direct route to the arteries at roughly the same speed.¹⁴

5.4 Construction of viewed variables

To populate the variables for windfarm viewed (VIEW) two methods were developed: a GIS simulated method and one involving field visits, and one method was ultimately used: the field visit method. The GIS method, as discussed in Appendix C, achieved an accuracy rate of 85% which improved on previous studies (Dean, 1997; Maloy and Dean, 2001) but did not meet accuracy requirements for this report's analysis of greater than 95%.

Therefore the second method involving field analysis was used to ensure complete accuracy of the "view" variables. Visits were made to each of the 280 homes which sold after Jan 1, 2001 and were within 5 miles of the windfarm (138 homes visited) to assess the degree to which the home could see the windfarm. By standing at or near the house a rating of 1 to 60 was established for each home. This rating was based on the degree to which viewers could see each of the 20 windmills in the Fenner windfarm (Figure III).

Figure IV: Turbine Visibility Scoring Method

¹⁴ A more accurate measurement would be a shortest elapsed time traveled incorporating speed limits of roads, and distance traveled on them. This is similar to the algorithms used by, for instance, Mapquest.

If the viewer could see only the top 1/3 of the turbine blades one point was given for that turbine, visibility of the nacelle (or hub) was a second point and visibility below the sweep of the turbine blades a third. Therefore a total of 3 points per turbine were possible, with a total of 60 points for the 20 turbines. No distinction was made for the direction the house faced because it was assumed purchasers were likely to walk around the house and inspect all views. If the turbines were clearly in view from the property surrounding the house, and the purchasers had a strong reaction to their visibility, it was assumed they were not likely to make a distinction between front, back and side windows at the time of purchase. Inspections were done on October 30 and 31, 2005 when deciduous trees had partially dropped their leaves. A slight distinction between winter (leaves off) or summer (leaves on) sale dates could be made from some properties; therefore visibility was calculated using the appropriate condition. Finally photographs of the house and of the predominant view were taken to corroborate results at a later time if needed.

Table III: Description of Viewshed Variables

DIS TO MILLS	The distance from the home to the nearest turbine as calculated by the GIS.
VIEW	The view of the turbines as recorded from the field analysis with possible range from 0 to 60. If house sold before Jun 1, 2001 the value is 0.
VIEW1MILE	The VIEW of the home if $0 < \text{DIS TO MILLS} < 1$, otherwise 0.
VIEW2MILE	The VIEW of the home if $1 < \text{DIS TO MILLS} < 2$, otherwise 0.
VIEW3MILE	The VIEW of the home if $2 < \text{DIS TO MILLS} < 3$, otherwise 0.
VIEW4MILE	The VIEW of the home if $3 < \text{DIS TO MILLS} < 4$, otherwise 0.
VIEW5MILE	The VIEW of the home if $4 < \text{DIS TO MILLS} < 5$, otherwise 0.
VIEW2001	The VIEW of the home if the year of sale was 2001, otherwise 0.
VIEW2002	The VIEW of the home if the year of sale was 2002, otherwise 0.
VIEW2003	The VIEW of the home if the year of sale was 2003, otherwise 0.
VIEW2004	The VIEW of the home if the year of sale was 2004, otherwise 0.
VIEW2005	The VIEW of the home if the year of sale was 2005, otherwise 0.

5.5 *Discussion of Descriptive Statistics*

Of the 280 properties in the sample, the mean value of homes was \$102,384, the mean number of acres was 8.8 and the mean age of the home at the time of sale was 42 years old. Approximately 28% of all the houses in the sample could see the windfarm; of the 149 sales that took place after January 1, 2001, 43 were from homes which could see the windfarm. A full description of all the variables is included in Appendix A.

5.6 *Testing for violations of OLS assumptions*

After the model had been constructed the data were tested in accordance with the ordinary least squares (OLS) assumptions which govern hedonic regression models. These assumptions include: multicollinearity, the independence of the error term and the independent variables, homoskedasticity and temporal autocorrelation.³⁵

5.6.1 Multicollinearity

The assumption of multicollinearity posits that the independent variables are in fact independent and not highly correlated with each other. If one variable is highly dependent on one or a combination of variables, the *p*-values will be inappropriately increased. This assumption can be tested for by regressing each independent variable on the others and then looking at the unadjusted R^2 values. Convention holds that R^2 values less than 0.75 indicate a multicollinearity low enough to allow results to be largely undisturbed (Halcoussis,

³⁵ A fifth assumption which is commonly considered in OLS models, but rarely in hedonic literature is simultaneity, when the dependent variable affects the independent variables. This was not directly tested for, but its effect on coefficient significance is to increase it. In the case of this report, this does not alter our results.

2005).¹⁶ In our case all R^2 values were under this threshold, and most (80%) were considerably under it (in the .5 to .2 range).

During initial analysis of the variables, a correlation matrix was generated. It was found that the number of bedrooms (NBR_BEDROOMS) was highly correlated (0.746) with square feet (SFLA), but the number of bathrooms (NBR_BATHROOMS) (0.474) and the number of half baths (NBR_HALF_BATHS) (0.361) were acceptably correlated with square feet and each other (0.044), so bedrooms was dropped from the model and half baths was added. Additionally it was found that distance to I90 (DIS_TO_I90) was highly negatively correlated to distance to Route 20 (DIS_TO_RT20) (-0.977) because they run roughly parallel to each other. Therefore, I90 was dropped from the model.

5.6.2 Independence of Error Term and Independent Variables

Independence of the error term and the independent variables is important in assuring that the variables are the best predictor of the dependent variable. To test this assumption, the residuals were regressed on the independent variables. None of the independent variables were significant (p -value range from 0.138 -- 0.913) and the model itself is non-significant (f -value 0.258, p -value 0.999, adjusted R^2 -0.059).

5.6.3 Homoskedasticity

Homoskedasticity of the variables assumes that the error terms of any range of values of a continuous variable are similar. The values of the variables are ordered in ascending or descending order and divided into thirds. The Levine test statistic compares the variances

¹⁶ Actually the measure used is the Variance Influence Factor (VIF) which is calculated as follows: $1/(1-R^2)$. A VIF of 4 or below is appropriate to reject the claim of a high degree of Multicollinearity. An R^2 more than 0.75 will result in a VIF more than 4.

of the thirds. If that statistic falls outside the acceptable range (p -value > 0.05) the assumption holds. In our case all continuous variables returned values exceeding 0.05 therefore the OLS assumption of homoskedasticity was met.

5.6.4 Temporal Autocorrelation

The existence of temporal autocorrelation violates the OLS requirement that the residuals are independent of each other. If temporal autocorrelation exists, the values of the dependent variable, and therefore their residuals, are affected by the value in the previous temporal term. By arraying the residuals in chronological order and testing the correlation of any residual against its preceding residual their autocorrelation can be determined. The Durbin Watson test statistic ranges from 0 to 4. Within a range of 1.5 to 2.5 there is considered to be no autocorrelation. A statistic either more or less than that range is considered to have either a positive or a negative autocorrelation respectively. All of the models had a Durbin Watson test statistic between 1.798 and 2.047, therefore no autocorrelation was detected.¹⁷

¹⁷ Spatial autocorrelation was not tested for, yet it is possible that it would exist within the data, following the logic that a neighbor's transaction value affects the surrounding transactional values both on the sellers and buyers side of the transaction.

6 Analysis

Results of the six models that were run are reported in Appendix F. Initially, the model was run with all potentially significant variables (Model #1), as recommended by the literature (Table I) and the local experts (Table II). Many building styles and school districts did not meet initial significance criteria (p -value < 0.75). As well, the variable for air conditioning (CENTRAL_AIR) was found to be insignificant. These variables were removed. As expected these changes improved the model's overall significance (Model #2). Model #3 is further refined with all non-significant (p -value > 0.1) variables removed except those for seasonality (e.g. FALL_SALE). This model (Model #3) had an F-value (63,764) considerably higher than that of Model #2 (39,185) indicating the removed variables created undue "noise" in the model. All variables had the expected sign except for the Fenner Township binary variable, which is discussed below. Model #3 was then used to test the significance of the viewshed variables.

Initially the variables for distance to the windmills (DIS_TO_MILLS) and view of the windmills (VIEW) were added to the model (Model #4). The coefficients for these variables were both positive yet non-significant at both the 95% or 90% levels of confidence (0.679 and 0.410 respectively). Models #5 and #6 explore the potential micro-spatial and temporal effects of view in 1 mile bands (VIEW1MILE thru VIEW5MILE) and subsequent years (VIEW2001 thru VIEW2005) respectively. Although both models are significant in general, all 10 variables did not meet the significance criteria (p -value < 0.10), therefore interpretation of the coefficient value or sign is not appropriate.

As mentioned above the sign (coeff. -0.083) and significance (p -value 0.018) of the binary variable for the Fenner Township (FENNER) is surprising. This variable measures

the marginal change in value for homes in Fenner Township as compared to all other townships. We included this variable to explore if the payment the township receives in lieu of taxes from windfarm operations (PILOT) has had an effect on the values of homes in the township all else being equal. The assumption is that if the payments, which largely go to the school system in the township, are considered to have significantly improved conditions in the township in the eyes of home purchasers, this variable would be both positive and significant. But, in our model the coefficient was negative and quite large (the coefficient -0.083 corresponds roughly to a decrease of 8%). Therefore, to further explore we added binary variables for all townships including Fenner (Smithfield was the omitted township). The results of this test indicated that none of the townships had a significant influence on price when taken together. This indicated that the influence of Fenner was being spread among the townships. Therefore, finally we omitted the Fenner variable and included all of the other township variables and found both Cazenovia (coeff. 0.106, p -value 0.095) and Nelson (coeff. 0.105, p -value 0.081) were significant and positive. Results for these variables are in Table IV. The positive sign implies that in relation to Fenner *ceteris paribus* the placement of the house in Cazenovia and Nelson adds value. We explored whether this had to do with the wind energy facility by adding view variables to the model. Because distance to turbines can be largely explained by the township variables¹⁸ we only included the variable VIEW [of turbines]. We found that neither the magnitude nor the significance for the township variables changed when we took view into account. This implies that the decreased value of homes in Fenner is not related to the wind facility. To investigate the effects of township further we contacted a local realtor (Arsenault, 2006).

¹⁸ Regressing distance on the township variables produced adj. R^2 of 0.579 and a p -value of 0.000.

He believed there was a correlation between the township (Fenner) and the value of homes, in that homes of higher values were not being built in the Township. He attributed this to the windmills, and believed that there was a correlation between values of home and the

Table IV: Testing for the Influence of Township on Home Value

F/Significance	53.921	0.000	51.184	0.000	46.524	0.000	48.827	0.000	41.132	0.000

Note. Non viewed variables were included in the model but were not shown above. Coefficients roughly correspond to percentages (e.g. 0.100 = 10% increase), and p-values correspond to the likelihood that this result was reached by chance (e.g. 0.100 = 10%).

affect "view of the turbines" had on them. He said, "Higher priced homes were not being built in the Fenner area because of the view of the turbines." To analyze this claim we broke sample set of home sales into thirds and investigated whether the variable for view was affected. In so doing we tested the claim that homeowners of higher priced homes care more about the view than those of lower value. Table V contains the results. We found that view did not have a significant effect at any price range. We also found that although splitting the groups did not affect the significance of the overall model, it did dramatically decrease the R² statistic as compared to previous models (roughly 0.80 to 0.23). A portion of this decrease can be explained by the decrease in the number of cases in each group (*n*).

Table V: Testing for Significance of View among 3 Price Levels

Price Level	Lower 3rd		Middle 3rd		Upper 3rd	
	Coeff.	p-value	Coeff.	p-value	Coeff.	p-value

VIEW	0.003	0.313	0.002	0.361	0.000	0.918
<i>n</i> /Adjusted R ²	92	0.471	93	0.226	92	0.627
F/Significance	6.13	0.000	2.507	0.003	9.605	0.000

Note: All non-viewshed variables were included in the model but are not shown above. Coefficients roughly correspond to percentages (e.g. 0.100 = 10% increase), and p-values correspond to the likelihood that this result was reached by chance (e.g. 0.100 = 10%).

but not all. It could reflect the variance between the income levels, and indicates a need for further research into how each income level makes home buying decisions, based on the non-viewshed variables that were included in the model (i.e. number of bathrooms, square feet, and number of acres).

7 Conclusions

Our analysis of 280 home sales within 5 miles of the Fenner windfarm, in Madison County, New York failed to uncover any statistically significant relationship between either proximity to or visibility of the windfarm and the sale price of homes. Additionally, the analysis in this report failed to uncover a relationship even when concentrating on homes within a mile or that sold immediately following the announcement and construction of the windfarm. Therefore it is safe to conclude, in this community, a view of the windfarm does not produce either a universal or localized effect, adverse or not. To the degree that other communities emulate the Fenner rural farming community, these results should be transferable. But, to be safe in these conclusions, let us first consider the possibility that: 1) effects exists, but the instruments which were used in this study were not effective in measuring them, and 2) effects exists but because those effects are situated outside the sample area our analysis did not discover them.

First we investigate the possibility: whether the instruments were not effective in measuring an effect. The instruments in question are 1) the hedonic pricing model and 2) the methods used to calculate turbine visibility. The hedonic model is appropriate as it has been well tested in various applications including, but not limited to, assessments, in valuing nearby open spaces and in valuing the effects of HVTL and environmental stigmas. It is particularly effective at discerning universal influences, and the question of effects on property values is not whether one or two houses are affected but rather if groups of houses are affected in a predictable universal way. The construction of the model, used in this report, follows the convention described as "test, test, test" (Kennedy, 2003), which refers to a model construction method that, "discovers which models of the economy are tenable,

and to test rival views.” (p. 83) By carefully testing the assumptions behind the model, as were described in section 5.8, the model that was ultimately chosen can be considered to be “the best estimated regression line” (Halecoussis, 2005).

In regards to the tests of “visibility” from each of the homes, the method chosen was intended to reduce bias and allow for a robust set of measurements (0 to 60). View was measured not in a subjective way, but rather by counting the numbers of points seen from the house. The distance was measured by linear calculations produced by a GIS. Because the range of the two measurements is relatively large, a small miscalculation of “view” (0-60 scale) or distance (0.00 to 5.99 miles) will not adversely affect the ability of the model to explain variations in sale price. It is therefore safe to say that the instruments this report used are both appropriate.

The second possibility of error concerns whether effects exist outside the sample area and therefore were not measured by our analysis. In other words, is it possible that a house inside of 0.76 miles, outside of 5 miles or that will sell after June 2005 will be affected differently than what our sample describes? The possibility should be investigated in other studies, but in the case of Fenner it is unlikely unless the situation on the ground changes.³⁹ Our sample set includes *all* arms-length transactions of single family homes which occurred from January, 1996 to June, 2005 within 5 miles of (and as close to 0.76 miles from) the windfarm. If one is to attempt to address the question of whether effects exist, a sample set containing *all* transactions cannot be improved upon.⁴⁰ If houses were

³⁹ For example, if the turbines are taken out of operation yet are not decommissioned or removed. Thayer (1987) found a strong negative reaction to just such a situation in California in the 1980s.

⁴⁰ The sample data is normally distributed as would be expected of 280 transactions. See Appendix F.

measurably affected outside the sample set, it seems unlikely that concurrently no effect, weak or strong, would be found inside the sample set.

If the potential inadequacy of the instruments has largely been ruled out, and we are confident that the study area represents an adequate sample we can conclude no effect exists for this community, or, if they do, the effects are random and therefore, by definition, unpredictable. The result of "no effect" has been corroborated by peer-reviewed large sample survey studies. Warren (2005) found, on average, windfarms were of little concern to residents stating, "The data reveal a clear pattern of public attitudes becoming significantly more positive following personal experience of operational windfarms" (p. 866). Further, Braunholtz (2003) finds,

"It is extremely rare for people to spontaneously mention their local windfarm as either a positive [$<3.0\%$ of sample] or negative [0.3% of sample] aspect of their area. This fact that suggests that, for most at least, [the windfarm] is not foremost in their minds when thinking of, and describing, the area" (p. 5).

A rural setting with a history of farming, these townships might accept harvesting wind energy as an extension of the use of their land. The wind farm does not seem to have been in contest with the sense of place that is mentioned in Devine-Wright's (2004) discussion. Possibly the non-linear layout is desirable. It is rather undulating as is the landscape itself. There are many opportunities for hide and reveal⁴¹ in this landscape, which might allow viewers to keep an emotional distance from the turbines if they are in opposition to them, or to look at them more affectionately if they are in favor of them.

⁴¹ "Hide and reveal" or "miegakure" (jap.) is a phrase used in landscaping where even in small spaces portions screening of features (the "hide") encourages viewers to see what lies just around that bend (the "reveal").

Thayer (1987) found that public sentiment was strongly tied to the bureaucracy behind the decision to erect the windfarm (local officials, developer). This is echoed by Wolsink (1989) and Krohn (1999), who states "decision making over the heads of local people is the direct route to protest" (p.959). In the case of Fenner the developer was required to prepare and submit for public review an EAF. And the Town of Fenner was the lead agency overseeing the approval of permits. Therefore, to the degree that the EAF process effectively addressed and corrected negative concerns, the community might not have retained much negative sentiment toward the project going into construction. Possibly the research of Devine-Wright (2004) offers an explanation. He states, "the opinions of significant others such as friends and family living in the local area are important in determining public perceptions of wind farms" (p.130). In Fenner, one civically involved couple who leased their land to the developer is not only a proponent of wind energy, but also talks with great pride of the Fenner Township and surrounding area. They host tours and offer t-shirts and hats for wind farm visitors. They might have influenced the community positively. In fact an imminent windfarm expansion in Fenner from 20 to 29 turbines has been met with no opposition. This matches with Warren's (2005) results. He samples residents both with and without experience living near windfarms and found those with experience are much more likely to favor expansion of them.

To the degree that other similar communities exist in the US, in that they have similar land uses, median home prices, and homeowner profiles, these results should be transferable. Extrapolation of these results to communities which do not fit this description, without careful consideration, is not recommended until more research is conducted. Specific recommendations for further research are outlined below.

8 Policy Implications and Recommendations

Contrary to the notion that adverse effects are universal, this report did not produce any significant relationship between distance from, or visibility of the windfarm and the sale prices of homes. These results fit with those reported in other empirical studies that surveyed public attitudes, which found that people living near turbines find them “acceptable” and, in fact, rarely spontaneously mention them (Braunholtz and MORI-Scotland, 2003). Together these studies suggest that in communities similar to the one surrounding the Fenner windfarm, the question of property value effects should be lessened in importance in the decision making process. Further, if these results are substantiated in further research as discussed below, the implications for stakeholders are significant.

Specific recommendations for many of the stakeholders in the windfarm planning process are as follows:

- **Town Officials/Planners:** Town planners should realize that the methods for facility approval can greatly contribute to placating community concerns. A transparent process which allows residents to address siting concerns such as the size of the project, the placement of the turbines as it relates to dwellings, and the provisions for dealing with maintenance and decommissioning are very important. If steps such as these are followed, local decision makers should be able to enjoy favorable community sentiment and avoid property devaluation.
- **Community Members:** This research should provide some confidence to community members that a windfarm siting does not guarantee a devaluation of property values, and that assertions to that effect should be thoroughly investigated. In fact, if more studies corroborate these findings devaluation might be considered unlikely. If residents

believe their community is similar to Fenner's, factors other than property devaluation should be concentrated on. These could include the level of payments in lieu of taxes (PILOT), the quality of decommissioning assurances and the level of transparency in the planning process. Based on the findings of this study these factors could play a more important role than potential property devaluation in a community's proposed windfarm evaluation process. Additionally, urging local, state and federal policy makers to promote continuing research into public attitudes surrounding other wind energy facilities will allow for greater understanding of upcoming development proposals, and a larger area of transferability of results.

- **State lawmakers:** This report's findings of "no effect" might indicate that the planning process used for the Fenner windfarm should be used as a model. Currently some state laws allow the review process to be entirely avoided (GAO, 2005), yet an environmental review and subsequent community involvement can help ensure that appropriate decisions are made and development is accepted by the community going forward. State regulations should require all wind developments to participate in the FIS process, to ensure that the planning process is transparent, and that community involvement is encouraged. Additionally, through an intense effort to research and disseminate findings, such as reactions of other communities to wind development in the U.S., lawmakers can give local officials the tools needed to weigh real costs and benefits. In so doing, decision makers can avoid having to rely on insufficient information and speculation.
- **Wind industry representatives:** Although these findings seem to show that property devaluation did not occur in the community surrounding the Fenner windfarm, it should

be clear that property value effects are strongly tied to public attitudes, a cooperative planning process, and might be influenced by characteristics not present in the Fenner community. These are discussed below and include the number of second homes, the proximity to the wind turbines, and the percentage of “vista” included in the home value. Accordingly, encouraging further empirical research of public attitudes and property transaction values surrounding wind developments might provide decision makers with the information needed to make appropriate decisions regarding development proposals going forward.

8.1 Future research considerations

For communities, especially ones that are not similar to Fenner, there is an intense need for more research. With this, policy makers and other stakeholders will have better answers to this contentious issue. More information is needed regarding the following categories:

- **Other windfarm communities:** Roughly 90 sites in the U.S. are larger than the Fenner site (AWEA, 2005d), and many of them would be appropriate for study. Sites should be chosen with a variety of socio-economic characteristics, windfarm sizes, and population densities. Studies should analyze homes closer than 4000 feet, and include variables for “vista,”⁴² level of community cooperation in approval process, degree that farming matches sense of place (such as the percentage of large tract vs. small), and whether homes are the primary or secondary residences.
 - **Distance:** This study contains homes only as close as 0.75 miles or 4000 feet to the turbines. HVTL studies have found effects exist only inside 500 feet

⁴² As discussed in footnote 8 on page 2

(Des-Rosiers, 2002). Future studies should find communities with homes closer than 0.75 miles, and preferably as close as 500 feet if they exist.⁴³

- **Vista:** This study does not include a separate measurement for "vista" (or good view) in its analysis. For example, Haughton (2004) finds that homes with a high percentage of "vista" represented in their value (such as might be found in homes on the coast) might be affected differently by wind development.
- **Cooperative Process:** The community studied in this report was at least partially involved in the planning process, in so far as they were invited to attend and submit comments at a number of meetings (Moore, 2005). The degree to which the project developer includes the community in the planning process of other communities might influence results (Warten *et al.*, 2005) and should be studied.
- **Sense of Place:** Anecdotal evidence implies that this community still largely embraces the farming nature of its past. How well wind energy "harvesting" fits with other community's sense of appropriate land use might also alter outcomes (Devine-Wright, 2004). Using an average tract size for a sample might be a proxy for this variable.
- **Size of Project:** The Fenner windfarm is 20 turbines. Because there is evidence that community's prefer smaller windfarms over larger ones

⁴³ Homes within 500 feet of the turbines, in this study area, were situated on the same parcels that had turbines, and therefore the homeowners received income from the windfarm owners. This coincidence could present complications in analysis of sale prices. Additionally, none were sold during the study period.

(Wolsink, 1989; SEI, 2003) studies conducted using homes surrounding facilities larger than 20 might reach different results.

- **Primary Residence:** This study does not include a separate variable describing if homes are primary residences or not. It is possible that homeowners of non-primary residences might be more sensitive to changes in their viewshed. Future studies should include this variable.
- **Other potentially analogous structures:** Although the research from HVTL is helpful in establishing potential effects of windfarms on property values, research concerning other infrastructures might be more applicable. For instance, investigating transaction value effects on coastal homes having views of offshore drilling platforms could shed light on the property value effects when a high “vista” value is present.
- **Comparisons of hedonic and survey results:** Because survey results are often used as a proxy for actual effects, studies to determine the appropriateness of these methods as it applies to windfarms would be very fruitful for policy makers. If combined hedonic and survey studies were conducted in communities with existing windfarms, which started before announcement and continued well after construction, policy makers and stakeholders could determine the applicability of using surveys to determine present and future property value effects.
- **GIS visibility determinations:** By continuing research into this area, and using the most up to date data, such as that being newly collected by light detecting and ranging (LIDAR) radar techniques, policy makers and stakeholders may find a very inexpensive method for determining visibility and therefore conducting analysis on communities.

43

By conducting and disseminating further research, policy makers and other stakeholders can more fully understand the subtle interaction between a view of windfarms and property values. As a result, they will have more appropriate tools to make well informed decisions regarding wind energy siting proposals. For now, it is safe to say property value effects are not guaranteed, and in fact, in the case of Fenner, do not seem to exist at all.

Appendix A: Definitions and Descriptions of Variables

Table VI: Definitions of Non-Viewshed Variables

ACRES	The number of acres in parcel
AGE_AT_SALE	The age of home at time of sale. Calculated by subtracting year built from Deed_Year
BLDSTYL-APRM	Building style binary variable equal to 1 for A-Frame houses and 0 otherwise
BLDSTYL-CAPE	Building style binary variable equal to 1 for Cape houses and 0 otherwise
BLDSTYL-CNTMP	Building style binary variable equal to 1 for Contemporary houses and 0 otherwise
BLDSTYL-COLNL	Building style binary variable equal to 1 for Colonial houses and 0 otherwise
BLDSTYL-CITG	Building style binary variable equal to 1 for Cottage houses and 0 otherwise
BLDSTYL-LOG	Building style binary variable equal to 1 for Log Cabin houses and 0 otherwise
BLDSTYL-OLDSTYL	Building style binary variable equal to 1 for Old Style houses and 0 otherwise
BLDSTYL-RANCH	Building style binary variable equal to 1 for Ranch houses and 0 otherwise
BLDSTYL-RSRNCH	Building style binary variable equal to 1 for Raised Ranch houses and 0 otherwise
BLDSTYL-SPLIT	Building style binary variable equal to 1 for Split Level houses and 0 otherwise
CAZENOVIA	Binary variable equal to 1 if township is Fenner, otherwise 0.
CENTRAL_AIR	House has central air conditioning
DIS_TO_I90	Distance from home to Interstate 190 in miles
DIS_TO_RT_20	Distance from home to State Route 20 in miles
DIS_TO_TOWN	Distance from home to nearest town center in miles
DEED_YEAR	Year of sale as recorded on the deed
DEED_YEAR_SQRD	Year of sale as recorded on the deed - Squared
FALL_SALE	Binary variable equal to 1 for transactions in quarter 4 and 0 otherwise
FENNER	Binary variable equal to 1 if township is Fenner, otherwise 0
LINCOLN	Binary variable equal to 1 if township is Lincoln, otherwise 0
LN_SALE_PRICE_95	Natural Log of Sale Price in 1995 dollars
NBR_BEDROOMS	Number of bedrooms house contains
NBR_FIREPLACES	Number of fireplaces house contains
NBR_FULL_BATHS	Number of full bathrooms house contains
NBR_HALF_BATHS	Number of half bathrooms house contains
NELSON	Binary variable equal to 1 if township is Nelson, otherwise 0
OVERALL_COND	Overall condition of home at time of last assessment
RBSMNT_TYP_DUM	Binary variable equal to 1 for full or finished basement and 0 otherwise
SALE_PRICE_95	Sale price converted to 1995 dollars
SCHDIS-CAZ	School district binary variable equal to 1 for Cazenovia school district and 0 otherwise
SCHDIS-CHTNGO	School district binary variable equal to 1 for Chittenango school district and 0 otherwise
SCHDIS-CNSTO	School district binary variable equal to 1 for Canastota school district and 0 otherwise
SCHDIS-MOHS	School district binary variable equal to 1 for Morrisville school district and 0 otherwise
SCHDIS-ONIEDA	Schoe' district binary variable equal to 1 for Onieda school district and 0 otherwise
SCHDIS-STKBRDG	Schoe' district binary variable equal to 1 for Stockbridge school district and 0 otherwise
SFLA	Number of square feet in the home
SMITHFIELD	Binary variable equal to 1 if township is Smithfield, otherwise 0.
SPRING_SALE	Binary variable equal to 1 for transactions in quarter 2 and 0 otherwise
SFONE_WALL_MAT	Binary variable equal to 1 for stone or brick exterior and 0 otherwise
SULLIVAN	Binary variable equal to 1 if township is Sullivan, otherwise 0
SUMMER_SALE	Binary variable equal to 1 for transactions in quarter 3 and 0 otherwise
WINTER_SALE	Binary variable equal to 1 for transactions in quarter 1 and 0 otherwise.

Table VII: Definitions of Viewshed Variables

DIS_TO_MILLS	The distance from the home to the nearest turbine as calculated by the GIS
VIEW	The view of the turbines as recorded from the field analysis, with possible range from 0 to 60. If house sold before Jan 1, 2001, the value is 0.
VIEW1MILE	The VIEW of the home if $0 < \text{DIS_TO_MILLS} \leq 1$, otherwise 0
VIEW2MILE	The VIEW of the home if $1 < \text{DIS_TO_MILLS} \leq 2$, otherwise 0
VIEW3MILE	The VIEW of the home if $2 < \text{DIS_TO_MILLS} \leq 3$, otherwise 0
VIEW4MILE	The VIEW of the home if $3 < \text{DIS_TO_MILLS} \leq 4$, otherwise 0
VIEW5MILE	The VIEW of the home if $4 < \text{DIS_TO_MILLS} \leq 5$, otherwise 0
VIEW2001	The VIEW of the home if the year of sale was 2001, otherwise 0
VIEW2002	The VIEW of the home if the year of sale was 2002, otherwise 0
VIEW2003	The VIEW of the home if the year of sale was 2003, otherwise 0
VIEW2004	The VIEW of the home if the year of sale was 2004, otherwise 0
VIEW2005	The VIEW of the home if the year of sale was 2005, otherwise 0

Appendix B: Map of Study Area

Fenner Windfarm Study Area

Ann's Lergli: Residential Sales Between January 1996 - June 2005

Appendix C: Technique for Creating GIS Viewshed Prediction Algorithm

A predicted view from each home was calculated using GIS techniques. The accuracy of the best performing predicted view was 85% as compared to actual view measurements. Since this did not meet confidence requirements, it was not used in the model.

To create a viewshed that effectively mimics the reality of a landscape the ground surface elevations as well the ground cover need to be simulated. In our case the 10 meter USGS DEM was used for surface elevations. The DEM was converted to a 3 dimensional ESRI raster file with the ARCGIS 9 "DEM to RASTER" algorithm using float and no z-value conversion. 10 meter data from the Multi-resolution Land Characterization (MRLC) Consortium⁴⁴ depicted the ground cover. Then by estimating heights for each ground cover type in our sample area, and reclassifying the raster fields to these heights, a raster addition was possible between the DEM and the MRLC. Four sets of heights for deciduous, conifer, and mixed forests, shrubs and grass (cultivated land) were tested (See Table IV). All other groundcover types were given a height of 0.

Table XI: Description of Heights for Ground Cover Raster Files (in feet)

Set	Conifer	Deciduous	Mixed	Grass & Shrubs
WINTER	100	0	50	5
80 NO-GRASS	80	70	75	0
80	80	70	75	5
100	100	90	95	10

⁴⁴ Partners include the USGS (National Mapping, Biological Resources, and Water Resources divisions), USEPA, the U.S. Forest Service, and the National Oceanic and Atmospheric Administration

Road and turbine location shapefiles were provided by the Madison County Tax Office, and a river shapefile was provided by the USGS National Map. House locations were derived as described in section 5.3. Because MRLC raster cells often spanned roads and covered houses and turbine locations, buffer shapefiles were created around each. 10 foot buffers were created around roads and houses, and 30 foot buffers surrounded turbines. To improve viewshed algorithm performance each raster grid (both DEM alone and DEM/MRLC additions) was converted to a triangulated irregular network (TIN) (Dean, 1997; Reeves, 2004). Z coordinates were not provided for the road, river, turbine, house shapefiles and accompanying buffers so these were derived from the DEM TIN. Buffers were added to the DEM/MRLC TINs using hard replace, and rivers were added using hardline which effectively erased all ground cover in the buffer areas and along the lines of the rivers. A map depicting the landscape is provided in Appendix D.

To calculate the viewsheds that simulated the 3 point score used in field analysis, three values for OFFSETA⁴⁵ were used corresponding to the heights on the turbines. The top height was 430 ft, the middle height was 328 ft and the lowest height was 210 ft. Additionally a value for OFFSETB of 10 ft was used.⁴⁶ Then the viewshed algorithm was run for the 20 "observation" points of the

⁴⁵ OFFSETA is the field name used by ESRI Arc viewshed algorithms of values of vertical distance in surface units that are added to the z-value of each cell as it is considered for visibility.

⁴⁶ OFFSETB is the field name used by ESRI Arc viewshed algorithms of values of vertical distance in surface units that are added to the z-value of the observation point.

turbines at each of the three heights (top, middle, lowest). This produced three 10 meter raster grids with values from 0 to 20 possible. All were added together to produce a grid with values from 0 to 60 possible. These raster values were extracted using the house point locations giving a discrete value (from 0 to 60) for each home in our sample set. Of the four sets of heights used to create the ground cover raster values originally (see Table IV) the 80 No-Grass set was best at neither over nor under predicting visibility (See results in Appendix C) but still did not meet confidence threshold of 95% that we had hoped for.

Suggestions for improving GIS viewshed predictions

The reasons we believe our estimates are off is because of inherent errors in the DEM which then transferred to our TIN surface. We test this theory by using 63 geodetic markers from the USGS which were within our study area. Roughly 15% (10/63) of the two elevations differ by more than 1%, which in some cases is more than 5 feet (max = 7 feet). The direction of the errors are 60/40 peaks to pits⁴⁷ ("peaks" = 37, "pits" = 26). Errors are smaller for the largest 26 peaks (mean = 1.51 feet) versus the largest 26 pits (mean = -2.76 feet). The errors in the viewshed calculations are well distributed between over predicting the homes' view of the turbines and under predicting it. Therefore, we conclude if the surface of the entire study area is similar in inaccuracies to the test points, predicted

⁴⁷ "Peaks" refers to points on the TIN that are at a higher elevation than the geodetic markers, and "pits" refers to the opposite, where the TIN surface is at a lower elevation than the marker.

viewshed inaccuracies could be entirely based on pits and peaks in the DEM. A 5-foot peak in the TIN surface could obscure a large portion of the landscape a few miles away from predicted visibility. Concurrently an observer on a 5-foot peak could be predicted to see a great deal more than actually can be seen. Methods for correcting or smoothing these errors were not investigated, and therefore additional research in this area would be important.

Another contributing factor for viewshed inaccuracies might be ground cover representation. It is observed in field analysis that canopy heights are not similar across all forests of the same type. For instance some deciduous forests have been planted in the last 15 years and have not grown to a mature height, while other forests are in late stage progression with mature heights. We use the same height for all forests of the same type. Further, square raster cells do not accurately depict non-uniform patterns of forest growth, and are particularly bad at depicting lines of trees that cross diagonally to the raster grid. Lastly the depiction of the top of the canopy is flat, but in reality the top is non-uniform. Field analysis proves it was possible to view turbines through the variation of the canopy. Combined these inaccuracies could add to the errors in our visibility prediction results. A smaller grid than 10 meters for the ground cover layer and access to ground cover data that includes z-values would greatly improve depiction and therefore viewshed analysis.

Appendix D: Results of GIS Viewshed Prediction Algorithm

Figure V: Four Sets of Predicted Views versus the Actual Readings

Note. Results for each set are arrayed in ascending order without regard to house location. Therefore the amount of difference for one set for a particular house might not be similar for another set. Results are for 129 separate view readings. It is important to note the relatively even distribution of differences between positive and negative implying that the predicted viewshed models were most likely effected by forces outside the model such as random errors in the DEM

Appendix E: Landscape Constructions for Viewshed Prediction

Figure VI: Depiction of the Study Area without Ground Cover

Figure VII: Depiction of the Study Area with Ground Cover

Figure V and VI notes: Groups of three red dots are top, middle and low heights of turbines, randomly spaced purple dots are houses sold after 2001, heavy grey lines are roads, thin blue lines are rivers and raised green areas are depictions of ground cover

Figure VII: 3D Rendering of Study Area

Note: Depiction has elevation exaggerated 10 times. Except for where indicated dots are houses which sold after 1996, and lines are township borders. If possible rendering should be viewed in color.

Background

With a growing reliance on wind energy to mitigate risks from energy security and global warming, a continuance of federal renewable energy tax credits, and a number of state incentive packages, U.S. states are seeing wind energy development grow at an unprecedented rate. Additionally windmill and windfarm sizes are increasingly large in order to capture greater efficiencies. Litigious conflicts have occurred between community members and facility developers or town planners over expected aesthetic impacts and their corresponding property value impacts. Changes in property values can potentially represent a large "hidden cost" borne by the community. Tom Grey, former Executive Director of the American Wind Energy Association (AWEA) ranks aesthetics and property values as the #1 concern of communities. Without proper analysis of this subject and a thorough understanding of effects on communities surrounding existing facilities, upcoming projects will be either needlessly delayed or inappropriately approved. Many opinions exist on the effects of wind development on surrounding property values, but no study to date has empirically analyzed the subject and actually visited the homes in the community to establish the degree of turbine visibility.

Purpose & Methods

This report analyzed property values surrounding a twenty turbine windfarm, constructed in 2001, in Madison County, New York to establish if any effects actually exist, and to set standards for future research. 280 arms-

length residential home sales within 3 miles of the windfarm and occurring between 1996 and 2006 were analyzed. A visit to each home was made and an unbiased scoring method was used (see left) to quantify the degree to which each of these homes could see the windfarm, and the distance from each home to the turbines. These and other characteristics obtained from the assessor records were incorporated into an econometric model to ascertain if the properties sale prices were uniquely affected by the windmill visibility

Results

The report finds no measurable effects of windmill visibility on property values (p value

0.410). This absence of evidence holds even when concentrating on homes within a mile (p-value 0.656) or on those that sold immediately following announcement in 2001 (p-value 0.742) (See right).

Conclusions & Recommendations

The report suggests a number of reasons why no effects were found: The windmill array fits the landscape, wind farming fits this community's "sense of place", the payments the community received 'balanced' any adverse impacts, a well respected landowner/proponent swayed others, and possibly residents swapped local impacts for global benefits. Further, the report offsets the possibility that effects are more myth than reality citing empirical survey studies conducted in Europe which report resident reaction to windfarms largely to be neither good nor bad but rather "acceptable" and another study which finds the local wind facility is rarely (- 3.0%) spontaneously mentioned in residents' descriptions of their surroundings. The author recommends further study of 6 to 10 other sites in the US to ascertain if his results can apply to many of the communities considering wind facilities currently across the county.

Choose the power of the next generation

Choose wind-generated electricity.

Your purchase of *NewWind Energy*[®] supports the development and growth of wind-generated electricity in New York, reducing the need for energy produced from other sources. By purchasing *NewWind Energy*[®] you can help the environment and make our communities even better places to live and work.

NYSEG is a member of the NYPA Group of companies

Sign up today to support

NEWWIND ENERGY
A PRODUCT OF COMMUNITY ENERGY

**A program for customers who want to help our environment
and make a difference for future generations.**

Purchasing just \$5 worth of wind-generated electricity every month for one year reduces carbon dioxide emissions the equivalent of planting 212 trees or not driving 2,707 miles. Wind energy generated in New York can offset close to 143 million pounds of carbon dioxide annually.

The small monthly charge of \$5 added to your monthly NYSEG bill covers the added expense of 200 kilowatt-hours of wind energy being delivered to the New York power grid. Rest assured NYSEG will continue to deliver your electricity safely and reliably.

I want to make a difference.

Wind energy and health

Are wind farms harmful to our health as sources of infrasound?

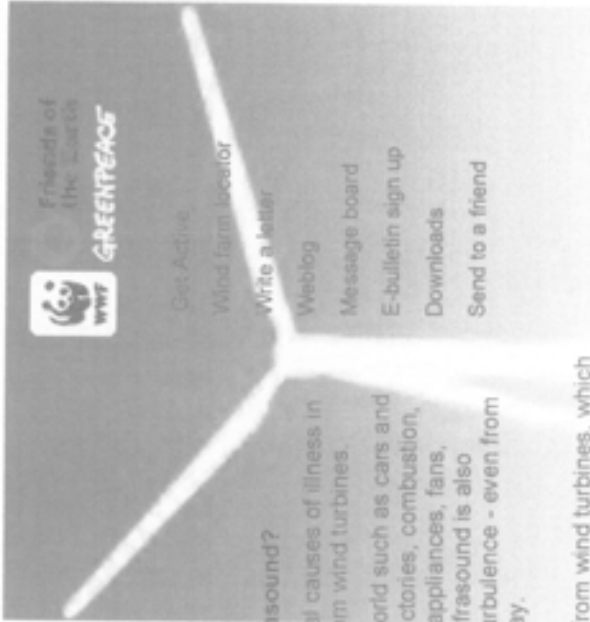

Infrasound and Low Frequency Noise are established as real causes of illness in some people, but there are no harmful infrasound effects from wind turbines.

There are all sorts of sources of infrasound in the modern world such as cars and other road traffic, aircraft, diesel engines, trains, shipping, factories, combustion, artillery, mining and quarrying, fridges and other household appliances, fans, compressors and pumps, music, TVs, and air conditioning. Infrasound is also ubiquitous in the natural environment from sources like air turbulence - even from earthquakes and storms, sometimes thousands of miles away.

Extensive work has already been carried out on infrasound from wind turbines, which demonstrated that "Low frequency noise and vibration levels were both found to comply with recommended residential criteria even on the wind farm site itself with the acoustic signal, below 20 Hz, being well below accepted thresholds of perception." In the words of one infrasound expert: "There are no harmful infrasound effects from wind turbines."

If a generator were to emit infrasound, the turbine tower would be affected, noticeably vibrating, and although at below audible sounds, this would be detected by the on board power control systems which monitor the wind turbine and would automatically shut it off.

Tens of thousands of wind turbines have now been operating worldwide for up to 20 years, including in some of the countries with leading general studies on infrasound. No link or problem has been identified with the presence of wind turbines in these studies.

Nevertheless, to be absolutely certain, it looks like the British Wind Energy Association might well ask for the Government's 'Noise Working Group' to be reformed and this work carried out again. Also, there are strict guidelines on noise, as prepared by the Working Group set up to address this issue back in 1996. Research on wind turbine noise has been carried out under the Department's New and Renewable Energy Programme. Copies of the reports 1 from those studies are available on the DTI website at www.dti.gov.uk/publications. See www.bwea.com/ref/noise.html for more details.

Winds have shaped the rugged West Texas landscape for ages. Now those winds are fueling a clean energy revolution that is revitalizing the West Texas economy. Since 1999, wind energy has infused the state with more than \$1 billion in capital investment, providing farmers, ranchers and local communities with new sources of income.

Wind energy is the fastest-growing source of power on the planet. With our tremendous wind resources, the United States can become a world leader in wind energy. Already, wind turbines in this country produce enough electricity to meet the needs of more than 1 million households. A single modern wind turbine can produce enough power to meet the annual electricity needs of 500 average homes.

In recent years the price of wind has fallen dramatically, making it increasingly competitive with fossil fuels. The federal government's National Renewable Energy Laboratory projects that the price of wind energy will fall even

further over the next decade, making it the most economically competitive renewable energy technology.

As a growing power source, wind energy can become a major force for economic development. Wind development can save consumers money and bring construction jobs, leasing royalties, and increased tax revenues to local communities. Supplying even 5 percent of the country's electricity with wind power by 2020 would add \$60 billion in capital investment in rural America, provide \$1.2 billion in new income for farmers and rural landowners, and create 80,000 new jobs.

Farmers and ranchers can also use wind power as a new "crop," earning \$2,000 per year in lease payments per turbine, helping insulate them from falling commodity prices. A single turbine takes up less than a quarter of an acre, including access roads, and farmers can grow crops or graze livestock right up to the base of the turbines.

How Does it Work?

Standing as tall as 300 feet to capture the full force of the wind, modern wind turbines use state-of-the-art technology to turn wind into electricity. When the wind blows, the blades begin to spin, turning an electric generator to create electricity. This electricity is carried through the turbine tower underground, where it feeds into the electric grid.

background

Environmental Benefits of Renewable Energy

Power plant air emissions are responsible for approximately one-third of nitrogen oxide emissions, two-thirds of sulfur dioxide emissions, and one-third of carbon dioxide emissions nationally. Renewables can avoid or reduce these air emissions, as well as reduce water consumption, thermal pollution, waste, noise, and adverse land-use impacts.

Moreover, renewables are sustainable energy resources: they avoid depletion of natural resources for future generations.

Renewables in a utility's generating mix can also reduce Clean Air Act compliance costs and make a region a more attractive place to do business by avoiding the imposition of costly emission-control measures in both the utility sector and in other industries and transportation. Under the Clean Air Act, emission reductions that are not achieved in one economic sector must come out of another.

Failure to capture cost-effective reductions in the utility sector will therefore require more stringent reductions from transportation and/or other industrial sectors, simply shifting rather than reducing costs. Because emission sources in those sectors are generally smaller and more numerous, they are generally more expensive to control. Moreover, most conventional emission-abatement measures in all sectors impose costs with no offsetting savings; renewables, on the other hand, produce fuel savings over their operating lives that cover some or all of their initial costs.

These environmental benefits can reduce the cost of complying with future environmental regulations as well. The science of environmental and health impacts of different pollutants develops unevenly. In addition, environmental regulators, faced with limited resources, must prioritize their activities. For these reasons, at any given moment environmental regulatory attention tends to be focused on a narrow range of environmental problems, or a single pollutant.

To meet incremental and piecemeal regulation of this kind, industry naturally turns to the compliance option with the

lowest short-run incremental cost, most often a bolt-on technology designed solely to mitigate the problem at hand. That technology then becomes a sunk cost which does not enter into cost-effectiveness calculations for responding to the next priority pollutant. Renewables, by contrast, especially zero-emission technologies, avoid these kinds of costs once and for all.

The risks of future environmental regulatory costs are not insignificant or unexpected, especially with respect to fine particulates and carbon dioxide. A growing body of public health research has found that emissions of particulates smaller than 2.5 microns are a major cause of premature deaths from air pollution. As the scientific consensus grows, and the costs of inaction are more closely understood, the likelihood of future regulations increases.

The same is true of global warming gases, especially carbon dioxide. In July 1996, 134 nations, including the United States, agreed in Geneva to negotiate legally binding reductions on emissions of heat-trapping gases. These reductions will be negotiated in Kyoto in December 1997. The agreement was based on the fact that in 1995 the Intergovernmental Panel on Climate Change had reached several new areas of scientific consensus.

The panel concluded for the first time that global temperatures have risen and that human activities are having a discernible effect on the climate system. It projects adverse impacts from sea-level rise and coastal flooding; severe stress on forests, wetlands, and other systems; damage to human health; and dislocation of agriculture and commerce.

The panel's report also points out that early action may allow greater future flexibility in choosing strategies for stabilizing emissions of heat-trapping gases. Renewables are particularly valuable in mitigating these risks and, consequently, in mitigating the risk of future expenditures to reduce heat-trapping gas emissions by other means. Carbon emission controls are not available by any known technology, and while natural gas plants emit only about half as much carbon dioxide as coal, they still contribute significantly to the problem and offer no long-term solution.

Renewables, on the other hand, including sustainably managed biomass, result in virtually no net carbon emissions. The availability of significant quantities of zero-emitting renewables could help to mitigate the environmental impacts of energy use, now and in the years to come.

NEWWIND ENERGY
A PRODUCT OF COMMUNITY ENERGY

A program for customers who want to help our environment and make a difference for future generations.

Increasing our 50-wind farm's generation capacity by 10% for one year reduces carbon dioxide emissions by 100,000 tons. That's the equivalent of planting 21,000 trees or not driving a 2000 car. Wind energy does not increase electricity rates. Our 100% wind-generated electricity program costs only \$5.00 per month. NewWind Energy is a 100% wind-generated electricity program that allows you to choose wind-generated electricity for your home or business. NewWind Energy is a 100% wind-generated electricity program that allows you to choose wind-generated electricity for your home or business.

Grant Money Will Encourage Local Windpower

HealthLink has received a grant to forward the installation of wind turbines in local communities. Through the awarding of this money, the Massachusetts Technology Collaborative is looking to HealthLink to assess the current state of interest in wind energy in North Shore coastal communities and to encourage the installation of wind turbines in each town or city. Who will own the turbines? What might suitable locations be? How soon will they pay back? HealthLink will hold public forums and meetings to present the issues to the public for discussion and as a basis for decision-making. HealthLink's volunteer core was pleased with the grant which will help them to continue their work to protect public health by reducing toxic pollutants in the environment.

"We are very excited about being given the financial support to spread the word about a technology that produces energy from a free, inexhaustible fuel which does minimal damage to the environment and produces no harmful emissions," stated Jody Howard, one of HealthLink's key volunteers on the wind project.

"Understanding all the health damage caused by burning fossil fuels, we have concluded that the only hope for a healthy future is renewable energy, and in the northeast, the only practical renewable is wind. With this grant, the hard work of figuring out how to install wind responsibly can begin in the community," said Jane Bright.

Added Gail McCormick, "Today's wind turbines are sleek, elegant and environmentally friendly. They are certified user-friendly by planet earth! Building a better tomorrow means taking action today!"

HealthLink has many plans to make the public aware of the benefits of wind energy. They include an Earth Day program at Salem State College with sessions, student research projects, and general activities open to the public; a spring wind festival on Lynn/Nahant causeway celebrating the power of wind, with participants' kite flying, sailing, windsurfing, twirling pinwheels, playing woodwinds, racing wind-powered go carts, and other wind-propelled devices; and working with local manufacturers and unions to develop a healthy turbine industry.

To launch the public awareness campaign, HealthLink is launching an information-gathering project. Travelers who have spotted wind turbines on their visits are asked to send photographs of these installations. These photos will be posted on the HealthLink website (www.healthlink.org) with informative descriptions and displayed in a traveling show.

"Clean air is our bottom line," said Lynn Nadeau. "Windpower is in the game. It's time to get off the bench!"

Solar and Ocean Energy

**Wind... Past and Present:
7,000 years of wind energy**

The Present:

2010

Pennsylvania, a coal state, will generate at least 10% of its energy from wind

2001

Denmark now produces 20% of its power from wind and aims to generate 50% of its electricity from renewable energy (primarily wind) by 2030

By year end 2000, the top countries for wind power

- Germany: 6,113 MW
- USA: 2,554 MW
- Denmark: 2,300 MW
- Spain: 2,235 MW
- India: 1,167 MW
- All others: 2,931 MW
- Worldwide: 32,300 MW**

The Past

Early 1900s AD: US: small wind turbines used to charge batteries and power radios and other small appliances

1890 AD: Denmark: first wind-driven electric generators, aka, the first true wind turbines

Uses over the next centuries included:

- grind grain
- pulverizing chalk, lime, oil seeds, snuff
- draining lowlands (Holland)
- pumping water for railroads, livestock, crops, and to run sawmills (especially in US)

1100 AD

France and England (and elsewhere): first horizontal axis windmills

600 AD

Persia: windmill building an established craft

200 BC

Persia: first evidence of windmill use

1600 BC

Babylon: plans to use windmills for irrigation

5000 BC

Egypt: wind carries boats along the Nile

Wind Pros and Cons, Myths and Misconceptions

Myths and Misconceptions

Myths about birds: Turbines kill: Today, turbines are built larger and more efficiently, and as a consequence, they rotate much more slowly than earlier versions (see them spin! [Link to video](#)). Even Audubon supports the development and use of wind power. (bird mortality stats p. 155-6, Berger; also, AWEA Wind Energy Fact Sheet. [Facts About Wind Energy & Birds](#))

A bird will collide with a given wind machine about once every 8-15 years; higher incidences may occur in locations with large concentrations of waterfowl or in areas of high migration

The only place where high mortality was found near wind facilities was Altamont (7,000 turbines), where 182 birds were found dead over a two year study. Collisions accounted for most of the deaths, the remainder were attributed to electrocutions from power lines, collisions with wires, and unknown causes

Each year, an estimated 57 million birds dies in collisions with vehicles, 1.25 million in

collisions with tall structures (buildings, towers), and 97.5 million in collisions with plate glass. (1994 Kenetech Windpower study results reprinted on AWEA fact sheet.)

Contrast this with deaths from the Exxon Valdez oil spill in Alaska, when more than 500,000 migratory birds perished (1,000 times the amount that die in California's plants each year); Or the 3,000 recorded bird deaths on one fall evening near a coal-fired power plant in Florida (AWEA Fact Sheet)

Myths about Turbines:

Noise - Again, technological advances enable more wind to be converted to rotational torque, which results in less noise. (dB comparison from AWEA slide presentation)

Unsafe - The only hazardous materials involved are small amounts of lubricating oils, and hydraulic and insulating fluids. As a result, soil contamination is minimal. Wind energy generators do, however, produce electric and magnetic fields (like all electrical generating facilities).

Expensive - Even without subsidies (due to expire in 2001), wind energy has become competitive with gas

Unreliable - While this might have been true in the 1980s, it's not true now. Modern turbines operate 98% of the time.

Unightly - Turbines are no longer small and noisy. Far fewer produce the same if not more power. Consequently, they can be spread out over a larger area and are less unsightly. Whether one perceives them as an eyesore or a thing of beauty depends on one's values.

Fossil fuels are cheaper than renewables like wind - the real reason they've been cheaper is the subsidies coal, oil and gas receive; plus, they don't account for environmental costs (in other words, fossil fuels are artificially cheap) - a carbon tax or tax breaks (government research and development funding) would even the playing field or even tip it in renewables' direction

It's difficult to integrate wind energy into existing utilities systems (i.e., the power grid) - Utilities companies, especially those in California, have been doing this successfully since the 1980s. According to a DOE-sponsored study (year TK), operators and dispatchers say engineering issues such as intermittent availability or voltage regulation are of no concern. From an operational standpoint, utilities carry adequate energy reserves so that

transmission disruptions (from turbine to supply lines, or from low wind conditions) would not result in power cuts to customers .. (from Wind Energy Weekly #680, 15 January 1996)

Photo by Bob Thresher of Searsburg, VT

Print out this table for easy reference. Then, see this link to answer wind power naysayers and inform others	
PROS	CONS
<p>Zero emissions - This means no CO₂, sulfur, nitrogen oxide, particulates, trace metals, or solid waste associated with global warming, acid rain, pollution, asthma, and other negative enviro/health consequences</p>	<p>High initial investment - About 80% goes to machinery, and 20% to site preparation and installation. After that, however, there are <i>minimal operating and routine maintenance expenses (no fuel to purchase!)</i></p>
<p>Renewable - Wind is in constant supply, unlike coal, oil, and gas, which are finite natural resources</p>	<p>Noise - Today's large wind turbines make less noise than the background noise you hear in your own home (45 dB versus 50 dB) (1)</p>
<p>Free - Because wind (not fuel) powers production, operation costs are effectively zero</p>	<p>Aesthetic/visual impact - Today's turbines are sleek and appealing to most people</p>
<p>Declining costs - As installed capacity has increased, costs have dropped 85% in 15 years to <50.05 per kWh. The DOE has set a goal of \$0.025 per kWh by 2002 (1)</p>	<p>Avian mortality - See Myths and Misconceptions</p>
<p>Creates new jobs? and new businesses, strengthening the U.S. economy</p>	<p>Intermittent - Wind must blow between 16 mph and 60 mph for power generation (2). At present, wind energy cannot be easily stored. Electricity providers are trained to divert other energy sources to meet demand, however, and storage technology (batteries) should improve markedly over time.</p>

<p>Quick installation - Once a site has been selected and permits approved, wind turbine installation can be completed in months (compared to years for a gas, coal, or nuclear plant)</p>	<p>Distribution - Wind turbines must be situated nearby existing infrastructure (transmission lines), or else costs escalate.</p>
<p>Phased growth - You can increase production capacity as your needs grow</p>	
<p>Mass appeal - Opinion polls consistently demonstrate strong popular support for clean-burning, renewable technologies like wind power</p>	
<p>Self-sufficiency - Because it can be developed domestically, wind power reduces U.S. reliance on imported energy</p>	
<p>Price stability - Unlike fossil fuel prices, which fluctuate due to factors beyond our control, wind power comes with a relatively fixed price, one likely to drop considerably over time</p>	
<p>Small footprint - Wind turbine towers interfere little with surface activity (e.g., farming, livestock)</p>	
<p>Low impact - Wind turbine operation offers little threat to wildlife and natural habitat</p>

Wind Energy

Wind turbines use energy from the motion of the wind to make mechanical energy, which is then converted to electrical energy. This, in turn, is fed into the utility grid and distributed to customers.

"Wind power, once a costly proposition on the flaky fringe of the energy debate, is going mainstream fast."

(U.S. News & World Report, Nov. 12, 2001, p. 36)

Wind power, like other renewable energy sources, is back on the public's agenda. The recent California energy crisis and nationwide rise in fossil fuel prices made sure of that. Fossil fuels are subject to extreme price fluctuations and more often than not influenced by geopolitical realities.

But U.S. reliance on finite supplies of fossil fuels is more than just risky business. Energy produced from these sources is dirty business. Sure, when prices are low, these sources are relatively easy on consumers' pocketbooks. But here are the hidden costs of fossil fuels, the so-called "cheaper" energy option:

- OIL spills...** Remember the Valdez?
- COAL spews...** greenhouse gases, carcinogens, particulates, etc.
- NATURAL GAS leaks...** harmful chemicals linked to asthma and other ailments

Add to this the liabilities of other traditional energy sources:

DAMS kill... not just fish, but entire river ecosystems
NUCLEAR frightens... no one wants radioactive waste buried in their backyard

Darkest areas of the map have the highest wind. Note the dark areas around the Massachusetts coast. Map by Dennis Elliot.

Wind power projects are ongoing in more than half of the country. CA, TX, IA, MN lead the nation in current output, but many other states, including MA, are potential "powerhouses."

WHY promote wind power?

No technology is perfect. We must weigh the benefits and costs of adopting wind power. Understanding both sides should lead to recognition that any tradeoff is a good one.

May 2006

Overview and Summary

In just five years from 2000-2005, wind energy has become a significant resource on many electric utility systems, with over 50,000 MW of nameplate capacity installed worldwide at the end of 2005. Wind energy is now "utility scale" and can affect utility system planning and operations for both generation and transmission. The utility industry in general, and transmission system operators in particular, are beginning to take note. At the end of 2005, the Power Engineering Society (PES) of the Institute of Electrical and Electronic Engineers (IEEE) published a special issue of its *Power & Energy Magazine* (Volume 3, Number 6, November-December 2005) focused on integrating wind into the power system. This document provides a brief summary of many of the salient points from that special issue about the current state of knowledge regarding utility wind integration issues. It does not support or recommend any particular course of action or advocate any particular policy or position on the part of the cooperating organizations.

The discussion below focuses on wind's impacts on the operating costs of the non-wind portion of the power system and on wind's impacts on the electrical integrity of the system. These impacts should be viewed in the context of wind's *total* impact on reliable system operation and electricity costs to consumers. The case studies summarized in the magazine address early concerns about the impact of wind power's variability and uncertainty on power system reliability and costs. Wind resources have impacts that can be managed through proper plant interconnection, integration, transmission planning, and system and market operations.

On the cost side, at wind penetrations of up to 20% of system peak demand, system operating cost increases arising from wind variability and uncertainty amounted to about 10% or less of the wholesale value of the wind energy.¹ These incremental costs, which can be assigned to wind-power generators, are substantially less than imbalance penalties generally imposed through Open Access Transmission Tariffs under FERC Order No. 888. A variety of means – such as commercially available wind forecasting and others discussed below – can be employed to reduce these costs. In many cases, customer payments for electricity can be decreased when wind is added to the system, because the operating-cost increases could be offset by savings from displacing fossil fuel generation.

Further, there is evidence that with new equipment designs and proper plant engineering, system stability in response to a major plant or line outage can actually be improved by the addition of wind generation. Since wind is primarily an energy – not a capacity – source, no additional generation needs to be added to provide back-up capability provided that wind capacity is properly discounted in the determination of generation

¹ These conclusions will need to be reexamined as results of higher-wind-penetration studies -- in the range of 25% to 50% of peak balancing-area load -- become available. However, achieving such penetrations is likely to require one or two decades. During that time, other significant changes are likely to occur in both the makeup and the operating strategies of the nation's power systems. Depending on the evolution of public policies, technological capabilities, and utility strategic plans, these changes can be either more or less accommodating to the natural characteristics of wind power plants.

capacity adequacy. However, wind generation penetration may affect the mix and dispatch of other generation on the system over time, since non-wind generation is needed to maintain system reliability when winds are low.

Wind generation will also provide some additional load carrying capability to meet forecasted increases in system demand. This contribution is likely to be up to 40% of a typical project's nameplate rating, depending on local wind characteristics and coincidence with the system load profile. Wind generation may require system operators to carry additional operating reserves. Given the existing uncertainties in load forecasts, the studies indicate that the requirement for additional reserves will likely be modest for broadly distributed wind plants. The actual impact of adding wind generation in different balancing areas can vary depending on local factors. For instance, dealing with large wind output variations and steep ramps over a short period of time could be challenging for smaller balancing areas, depending on the specific situation.

The remainder of this document is divided into four sections: wind plant interconnection, wind plant integration, transmission planning and market operation, and accommodating more wind in the future.

Wind Plant Interconnection

- Wind power plant terminal behavior is different from that of conventional power plants, but can be compatible with existing power systems. With current technology, wind-power plants can be designed to meet industry expectations such as riding through a three-phase fault, supplying reactive power to the system, controlling terminal voltage, and participating in SCADA system operation.
- Increased demands will be placed on wind plant performance in the future. Recent requirements include low voltage ride-through capability, reactive power control, voltage control, output control, and ramp rate control. Future requirements are likely to include post-fault machine response characteristics more similar to those of conventional generators (e.g., inertial response and governor response).
- Better dynamic models of wind turbines and aggregate models of wind plants are needed to perform more accurate studies of transmission planning and system operation.
- In areas with limited penetration, modern wind plants can be added without degrading system performance. System stability studies have shown that modern wind plants equipped with power electronic controls and dynamic voltage support capability can improve system performance by damping power swings and supporting post-fault voltage recovery.
- Because of spatial variations of wind from turbine to turbine in a wind plant - and to a greater degree from plant to plant - a sudden loss of all wind power on a system simultaneously due to a loss of wind is not a credible event.

Wind Plant Integration

- Utility planners traditionally view new generation primarily in terms of its capacity to serve peak demand. But wind is primarily an energy resource. Its

primary value lies in its ability to displace energy produced from the combustion of fossil fuels and to serve as a hedge against fuel price risk and future restrictions on emissions.

- The addition of a wind plant to a power system does not require the addition of any backup conventional generation since wind is used primarily as an energy resource. In this case, when the wind is not blowing, the system must rely on existing dispatchable generation to meet the system demand.
- Wind plants provide additional planning reserves to a system, but only to the extent of their capacity value. Capacity for day-to-day reliability purposes must be provided through existing market mechanisms and utility unit commitment processes.
- The capacity value of wind generation is typically up to 40% of nameplate rating, and depends heavily on the correlation between the system load profile and the wind plant output.
- The addition of a wind plant to a power system increases the amount of variability and uncertainty of the net load. This may introduce measurable changes in the amount of operating reserves required for regulation, ramping and load-following. Operating reserves may consist of both spinning and non-spinning reserves. In two major recent studies, the addition of 1,500 MW and 3,300 MW of wind (15% and 10%, respectively, of system peak load) increased regulation requirements by 8 MW and 36 MW, respectively, to maintain the same level of NERC control performance standards.
- Fluctuations in the net load (load minus wind) caused by greater variability and uncertainty introduced by wind plants have been shown to increase system operating costs by up to about \$5/MWH at wind penetration levels up to 20%. The greatest part of this cost is associated with the uncertainty introduced into day-ahead unit commitment due to the uncertainty in day-ahead forecasts of real-time wind energy production.
- The impact of adding wind generation can vary depending on the nature of the dispatchable generating resources available, market and regulatory environment, and characteristics of the wind generation resources as compared to the load. Dealing with large output variations and steep ramps over a short period of time (e.g., within the hour) could be challenging for smaller balancing areas, depending on their specific situation.
- Wind's variability cannot be treated in isolation from the load variability inherent in the system. Because wind and load variability are statistically uncorrelated, the net increase of variability due to the addition of wind is less than the variability of the wind generation alone.
- Commercially available wind forecasting capability can reduce the costs associated with day-ahead uncertainty substantially. In one major study, state-of-the-art forecasting was shown to provide 80% of the benefits that would result from perfect forecasting.
- Implementation of wind-plant-output forecasting in both power market operation and system operations planning in the control room environment is a critical next step in accommodating increasing amounts of wind penetration in power systems.

Transmission Planning and Market Operation

- Upgrades or additions to transmission facilities may be needed to access locations with large wind-energy potential. Current transmission planning processes are able to identify solutions to transmission problems, but the time required for implementation of solutions often exceeds wind-plant permitting and construction times by several years.
- ♦ Well-functioning hour-ahead and day-ahead markets provide the best means of addressing the variability in wind plant output.
- ♦ Energy imbalance charges based on actual costs or market prices provide appropriate incentives for accurate wind forecasting. Since wind plant operators have no control over the wind, penalty charges applied to wind imbalances do not improve system reliability. Market products and tariff instruments should properly allocate actual costs of generation energy imbalance.
- Wind turbine output or ramp rates may need to be curtailed for limited periods of time to meet system reliability requirements economically.
- Consolidation of balancing areas or the use of dynamic scheduling can improve system reliability and reduce the cost of integrating additional wind generation into electric system operation.

Accommodating More Wind in the Future

- Understanding and quantifying the impacts of wind plants on utility systems is a critical first step in identifying and solving problems.
- ♦ A number of steps can be taken to improve the ability to integrate increasing amounts of wind capacity on power systems. These include:
 - Improvements in wind-turbine and wind-plant models
 - Improvements in wind-plant operating characteristics
 - Carefully evaluating wind-integration operating impacts
 - Incorporating wind-plant forecasting into utility control-room operations
 - Making better use of physically (in contrast with contractually) available transmission capacity
 - Upgrading and expanding transmission systems
 - Developing well-functioning hour-ahead and day-ahead markets, and expanding access to those markets
 - Adopting market rules and tariff provisions that are more appropriate to weather-driven resources
 - Consolidating balancing areas into larger entities or accessing a larger resource base through the use of dynamic scheduling.

Subject: Setbacks and Request for Correction, etc./Wets Impact on Weatherpatterns

Hi Calvin-

It was a pleasure speaking with you the other week. Feel free to call anytime with your questions or if you are having difficulty viewing any of the videos, etc.

Thanks for generous gift. It wasn't necessary but sincerely appreciated.

Enclosed with this email is the contents of dialogue regarding set-backs of WT from residential areas. Fenner, NY is included in the discussion.

Additionally, you may wish to check out the following link to a thesis (2MB PDF download) concerning the impact of WTs to change weather patterns, etc. Larry McGuinn, a friend and neighbor comments below on his reading of the document. The link follows his comments and then the comments about setbacks.

Thanks again and I wish you well with you efforts to let the truth about WTs be known in your area.

God Bless,
 Paul

Subject: Re: Another article!

It worked, read this over last nite...very interesting. If you noticed the fields were 30m or over 30 miles off shore, well out of the visual impact range and yet they had an effect on rain fall on land. You might send this to Paul and see if he would want to put on his computer and show at a meeting. The pics on the first page were impressive.

----- End of Forwarded Message

before sunset. The setback requested to address this problem is **2300'**, which is equivalent to 10 rotor diameters for the GE 1.5s towers previously mentioned by Ecogen for this project. The setback would need to be farther for turbines with larger rotor diameters. Again, AFP is willing to accept mitigation. In this case, the shadow flicker can be mitigated by turning off the rotor during the problem periods. However, we have no confidence that the wind farm operator will do so unless stiff penalties were in place for non-compliance.

Viewshed is very difficult to mitigate, considering the fact that these towers will be visible up to 20 miles away. This is one of the reasons to aggregate the towers in one location - a designated or de facto industrial park - rather than spreading them across the town in-between the properties and house of non-participating landowners. AFP requested setbacks of **5 miles from historic sites**, which is consistent with State Historic Preservation Office guidelines. To my knowledge, there are at least 3 historic sites which would be affected by the project as currently structured: two in the Village of Naples (located in an adjacent Town, which will be affected by the project) and the Narcissa Prentice house in Prattsburgh.

We also requested setbacks of a **half-mile from major roads** for highway safety. To my knowledge, the only major road which would be affected is Route 53. For example, Palm Springs, CA has an ordinance requiring a half-mile setback from highways. When you get the copy of the presentation, please note the superimposition (to scale) of the 384' GE 1.5s wind towers on Knapp Hill, which rises 520' above (and directly alongside) Route 53. Imagine driving down this corridor with some of these towers near the edge of the cliffs above the road. We feel this distraction to drivers will constitute a **road hazard of colossal proportions**.

Of the setbacks mentioned at the 11/18/04 SCIDA meeting, the **SHORTEST** was **1536'**. This is for safety protection from **ice throw** when dealing with a tower/turbine with a total height (to the top of the blade) of 384'. 384' (80' taller than the Statue of Liberty from the top of the tide to the tip of the torch) is the total height of the specific version of the GE 1.5s windtower which Ecogen initially indicated to SCIDA and AFP that they would be using. Ecogen now appears to be keeping its options open to select a larger windtower, such as the GE 2.7. Global Winds Harvest has also mentioned using larger towers. **For these larger towers, the requested minimum setback to address ice throw (alone) would be 1800'** as stated in data from Germany for these larger (and taller) towers.

As noted above, there are a number of serious health, safety, noise and viewshed concerns which can only be adequately addressed by placing these windtowers a significant distance from the property lines of non-participating landowners.

You requested a brief clarification. Here is my best effort, which you are free to excerpt.

"While the requested setback for high-frequency noise will vary (being site-specific), Advocates for Prattsburgh anticipates that noise studies following the 10/1/04 DEC Guidelines will lead to setbacks from property lines of 2200' to 3000'. This distance would also safely protect landowners from ice throw, and most probably, from shadow flicker. A half-mile setback from major roads is warranted for highway safety. Consistent with SHPO guidelines, a 5 mile setback should be honored from historic sites. A one-mile setback (or effective mitigation) can address the potentially harmful health effects from low-frequency noise."

The NYS PSC projects that we will have 1300 wind towers within the next 3 years, most of them in Western New York. There are currently NO REGULATIONS in New York to protect citizens from the inappropriate siting of these massive towers. SCIDA has the opportunity to show New York how this project can be done right, and we hope they rise to the challenge. Thanks again for your interest in what will be a critical issue for Prattsburgh, Steuben county and all of New York.

Please feel free to contact me should you need any further clarification.

Best regards,

John,
Thank you for an excellent reply.
Cynthia

Subject: Setbacks and Request for Correction

Rob Price
Steuben Courier Advocate

Dear Rob,

It was a pleasure speaking with you this afternoon about the Advocates for Prattsburgh (AFP) presentation to SCIDA on 11/18/04 and we appreciate your covering and writing about the meeting for the Steuben Courier Advocate. As we discussed, I will be sending you a hard copy of the Power Point presentation, in which we mentioned specifics regarding setbacks from the property lines of non-participating landowners. I mentioned this because **AFP did NOT specifically request a blanket 1500' setback from property lines.** What we requested and explained were various needs for setbacks which would adequately address *health, safety, noise and viewshed* issues. The minimum setback requirements are not arbitrary, as the need for setbacks varies with the nature of the problem which needs to be addressed and the siting of the towers. The setbacks are referenced to the **requirements necessary to adequately address specific problems** which will occur if these machines are placed between the homes and properties of non-participating landowners.

One of the most important (and easily regulated) setback is for **high-frequency noise.** We referenced the 10/1/04 letter from the DEC to SCIDA indicating how noise studies should be conducted at the **property lines** of non-participating landowners, when the leaves are off the trees, from the precise location of each tower. I will be sending you this DEC letter in a separate e-mail. As we discussed, Pastor Danley's house in Fenner is over 2000' away from the nearest tower, and the noise problem, at times, at her location is quite bad. Considering this and other information and data we have, AFP would NEVER request a noise setback of only 1500'. The background noise level at some of the property lines near proposed tower locations is in the range of 34-36dB(A). I can tell you this: where I have my house, it's QUIET. Because of the low background noise, it is more probable that actual noise setbacks consistent with the 10/1/04 DEC guidelines would be in the range of 2200-3000', dependent of course, upon local conditions.

We also mentioned setbacks of at least **1 mile for low frequency noise**, the sub-audible noise which can make people sick. (Please see the attached article. I can provide more information should you need it.) For example, the city of Riverside, CA has an ordinance requiring a 2 mile setback for wind towers, **unless** the manufacturer can prove that the machine model in question will not produce any impulsive, tonal noise in the low frequency range. While AFP is potentially willing to accept a manufacturer's guarantee as mitigation for low frequency noise, we will first need to get the straight story from GE Wind Energy in Tahachapi, CA. As you and I discussed, when pressed for specifications the manufacturer has been non-responsive, claiming that virtually all technical information is "proprietary". Then they refer us to a cheerful person in Marketing, who thus far has acknowledged no problems resulting from the operations of these wind towers under any circumstances whatsoever. This has not been reassuring.

Shadow flicker - reflections of the sun off the blades - can turn each rotor into a giant strobe generator. Shadow flicker can cause seizures and migraines in susceptible individuals. This flicker effect occurs primarily during the first 60-90 minutes after sunrise and the first 60-90 minutes

Migrating geese force energy firm to scrap plans for wind farm

JOHN ROSS

A POWER company has dropped plans for a wind farm because of fears that geese could be killed by the turbines.

Perth-based Scottish & Southern Energy (SSE) wanted to build the 56-turbine, 116 megawatt development at Broubster Leans in Caithness, a site of European nature conservation importance.

However, a two-year bird study showed that the wind-farm site would be under the flight route of migrating Greenland white-fronted geese and greylag geese which roost in the area. SSE decided that a wind farm would pose a significant risk of collision for the birds and dropped the proposals.

Dr Brian Smith, SSE's head of projects, said: "The development of more wind farms in Scotland is vital if we are to maintain secure supplies of power and tackle the huge risks to our country posed by climate change. But each potential site must be considered on its merits and be the subject of detailed scrutiny.

"Our work has shown that a wind farm at Broubster would not be sufficiently compatible with other environmental concerns, and so we have decided not to progress this further."

Anne McCall, head of planning and development for the Royal Society for the Protection of Birds, said: "The development of sensibly located renewable energy developments is one important means of tackling climate change.

"That SSE has resolved not to develop on this environmentally sensitive site is enormously welcome

and is an approach we commend to all those involved with the renewables industry." Comment # 264

About 14,000 Greenland white-fronted geese visit the UK each year with about 25 pairs stopping in Caithness.

A Scottish Natural Heritage report this week showed that geese are returning to winter in Scotland in some of the highest numbers recorded since their populations crashed in the early 20th century.

The report found that numbers of pink-footed geese, Greenland white-fronted geese, greylag geese and two types of barnacle goose have recovered significantly in recent decades.

Numbers of Greenland white-fronted geese in Scotland reached a peak of 21,164 in 1998-9 and, after a period of stability, is now showing signs of a decline to 17,500.

The population of Icelandic greylag geese peaked at 115,000 in 1990, followed by a decline to about 73,000 in 2002.

The report said goose populations remain extremely vulnerable to changing circumstances in their Arctic breeding grounds and their migration stopovers.

Windmills prove deadly to bats

Appalachian wind turbines are part of effort to develop clean source of energy, but they're killing thousands of bats.

By Larry Lipman

WASHINGTON BUREAU

Saturday, November 12, 2005

THOMAS, W.Va. -- Towering up to 228 feet above the Appalachian Mountain ridge, windmills are lined up like marching aliens from "War of the Worlds."

Up close, they emit a high-pitched electrical hum. >From a distance of a few hundred yards, their 115-foot blades make a steady whooshing sound as their tips cut through the air.

Owned by **FPL Energy**, a Florida-based company, they are part of the national effort to develop diverse and more environmentally friendly sources of energy.

The problem is, they're killing thousands of bats a year.

"I can appreciate that we need other energy sources," said Jane Burch, who lives in neighboring Grant County, W.Va., where a large wind farm has been proposed. "But I don't like the look of them, and I don't want them behind my property, and I don't like what they do with the bat kills."

The first wind turbines to generate electricity were erected about 25 years ago in California. But wind power capacity more than doubled from 2000 to 2004, and now turbines are found in **31 states**.

Though wind still generates less than 1 percent of the nation's electricity, the Department of Energy has set a goal of raising that to at least **5 percent by 2020**. To reach that goal, the **American Wind Energy Association estimates, it will require an increase from about 16,000 turbines nationwide now to more than 78,000 turbines**.

About **600 of those turbines are planned for West Virginia and Pennsylvania**. If they are built, **more than 50,000 bats a year could be killed in these two states alone**, said Merlin Tuttle, founder and president of Austin-based Bat Conservation International Inc.

He said there are no good estimates of how many bats would be killed nationwide if the association's projection of 78,000 turbines were reached, but he estimated that it would be far higher than 50,000.

"They can't sustain that kind of kill rate," Tuttle said, noting that bats are among the slowest-reproducing mammals, generally having one pup each year.

"Bats are just as important by night as birds are by day," he said. Indeed, bats play an important ecological role by eating mosquitoes and such crop-destroying insects as moths, locusts and grasshoppers.

Contrary to popular belief, bats have quite good vision. It's enhanced by echolocation that helps them "see" in the dark and enables them to zero in on insects as small as a gnat.

A study conducted at **FPL's Mountaineer Wind Energy Center this year indicated that its 44 turbines might**

have caused between 1,300 and 2,000 bat deaths in a six-week period.

That study was led by Edward Arnett, a scientist with Bat Conservation International, and financed largely by the American Wind Energy Association and its 700 member companies.

During the study, one of the turbines at Mountaineer was out of service. It was the only turbine where no bat fatalities were recorded during the entire period.

That led bat enthusiasts to conclude that **bats are not colliding with stationary blades; they're being hit by moving blades, said Dan Boone**, a wildlife biologist from Bowie, Md., who has joined the fight against new windmill farms on forested mountaintops.

Experts don't know why the mortality rate might be so much higher at wind facilities in the Appalachian Mountains than elsewhere in the country.

A Government Accountability Office report in September showed that at wind farms outside the Appalachians, fewer than one to four bats were killed each year per turbine. But Arnett said **the GAO report summarized studies that might have focused on birds and underestimated bat kills.**

It's also unclear precisely why bats are killed by windmills. Among the theories: The windmills are located in the bats' migratory path; bats might be attracted by the turbines' humming sound, their flashing aircraft-warning lights or their tail masts suitable for roosting; the short range of the bats' echolocation does not give them time to avoid the blades.

The recent Mountaineer study has led to an impasse between bat conservationists and the wind power industry over what to do next.

Conservationists have called for further studies that would disengage some turbines on nights when the wind speed is low and bats and their prey are more likely to fly.

The wind power industry has rejected that suggestion. It has proposed studies of deterrent measures such as acoustics to discourage bats from approaching the turbines.

"We don't think it makes a whole lot of sense to be focusing on a solution that potentially could reduce the amount of power that is generated and potentially put stress on the machines," said Steve Stengel, an FPL Energy spokesman.

"We think there needs to be a great deal of effort put into finding ways for bats and wind turbines to coexist," he said.

The wind power industry echoes the views of FPL Energy, according to Tom Gray, deputy executive director of the American Wind Energy Association.

Because wind power companies have been trying to produce energy more cheaply, any proposal that would reduce generating capacity and drive up costs would give the industry "heartburn," Gray said.

Acoustical deterrent efforts currently are in the design stage and might be tested in the laboratory by early next year, Arnett said. If preliminary investigations show promise, field tests might take place next year. FPL Energy has offered to allow some of its facilities to be used for such tests.

But Arnett and Boone noted that acoustic efforts to rid houses of bats rarely work and said they do not believe that sound deterrents would be effective in shielding turbines.

Emotions are running high along the Appalachian ridge as more wind farms are being considered.

Opponents argue that the facilities not only kill bats and disturb other wildlife habitat but are an eyesore, create noise pollution, startle livestock with the flickering of sunlight through the blades, decrease property values and could harm tourism on scenic mountain ridges.

"I can't say I would forever be against wind power, but as far as windmills on mountaintops, there ought to be more study before they just put up these windmills willy-nilly," said Burch, who is retired from the construction industry. "What happens if, in 10 years, wind energy is not working? Who is going to pay to bring them down? It's going to be the counties and the landowners."

William Smith, executive director of the Convention and Visitors Bureau and the Tucker County Chamber of Commerce, said the Mountaineer facility in his county has created a few jobs and brought in more money to local

government.

The wind facilities also produce electricity for thousands of homes "without effluent, smoke, nuclear waste, fly ash and other sorts of materials that are associated with alternative forms of electrical generation," Smith said.

As for tourism, though the wind farms do not attract tourists to the area, Smith said those who come for the spectacular fall foliage and the winter skiing also show an interest in seeing the windmills.

"They're not attracting people, but they're an attraction once people have arrived," he said.

Subject: Setbacks and Request for Correction, etc /Wets Impact on Weatherpatterns

Hi Calvin-

It was a pleasure speaking with you the other week. Feel free to call anytime with your questions or if you are having difficulty viewing any of the videos, etc.

Thanks for generous gift. It wasn't necessary but sincerely appreciated.

Enclosed with this email is the contents of dialogue regarding set-backs of WT from residential areas. Fenner, NY is included in the discussion.

Additionally, you may wish to check out the following link to a thesis (2MB PDF download) concerning the impact of WTs to change weather patterns, etc. Larry McGuinn, a friend and neighbor comments below on his reading of the document. The link follows his comments and then the comments about setbacks.

Thanks again and I wish you well with your efforts to let the truth about WTs be known in your area.

God Bless,
 Paul

It worked, read this over last nite...very interesting. If you noticed the fields were 30m or over 30 miles off shore, well out of the visual impact range and yet they had an effect on rain fall on land. You might send this to Paul and see if he would want to put on his computer and show at a meeting. The pics on the first page were impressive.

before sunset. The setback requested to address this problem is 2300', which is equivalent to 10 rotor diameters for the GE 1.5s towers previously mentioned by Ecogen for this project. The setback would need to be farther for turbines with larger rotor diameters. Again, AFP is willing to accept mitigation. In this case, the shadow flicker can be mitigated by turning off the rotor during the problem periods. However, we have no confidence that the wind farm operator will do so unless stiff penalties were in place for non-compliance.

Viewshed is very difficult to mitigate, considering the fact that these towers will be visible up to 20 miles away. This is one of the reasons to aggregate the towers in one location - a designated or de facto industrial park - rather than spreading them across the lawn in-between the properties and house of non-participating landowners. AFP requested setbacks of **5 miles from historic sites**, which is consistent with State Historic Preservation Office guidelines. To my knowledge, there are at least 3 historic sites which would be affected by the project as currently structured: two in the Village of Naples (located in an adjacent Town, which will be affected by the project) and the Narcissa Prentice house in Prattsburgh.

We also requested setbacks of a **half-mile from major roads** for highway safety. To my knowledge, the only major road which would be affected is Route 53. For example, Palm Springs, CA has an ordinance requiring a half-mile setback from highways. When you get the copy of the presentation, please note the superimposition (to scale) of the 384' GE 1.5s wind towers on Knapp Hill, which rises 520' above (and directly alongside) Route 53. Imagine driving down this corridor with some of these towers near the edge of the cliffs above the road. We feel this distraction to drivers will constitute a **road hazard of colossal proportions**.

Of the setbacks mentioned at the 11/18/04 SCIDA meeting, the **SHORTEST** was 1536'. This is for safety protection from **ice throw** when dealing with a tower/turbine with a total height (to the top of the blade) of 384'. 384' (80' taller than the Statue of Liberty from the top of the base to the top of the torch) is the total height of the specific version of the GE 1.5s windtower which Ecogen initially indicated to SCIDA and AFP that they would be using. Ecogen now appears to be keeping its options open to select a larger windtower, such as the GE 2.7. Global Winds Harvest has also mentioned using larger towers. **For these larger towers, the requested minimum setback to address ice throw (alone) would be 1800'** as stated in data from Germany for these larger (and taller) towers.

As noted above, there are a number of serious health, safety, noise and viewshed concerns which can only be adequately addressed by placing these windtowers a significant distance from the property lines of non-participating landowners.

You requested a brief clarification. Here is my best effort, which you are free to excerpt.

"While the requested setback for high-frequency noise will vary (being site-specific), Advocates for Prattsburgh anticipates that noise studies following the 10/1/04 DEC Guidelines will lead to setbacks from property lines of 2200' to 3000'. This distance would also safely protect landowners from ice throw, and most probably, from shadow flicker. A half-mile setback from major roads is warranted for highway safety. Consistent with SHPO guidelines, a 5 mile setback should be honored from historic sites. A one-mile setback (or effective mitigation) can address the potentially harmful health effects from low-frequency noise."

The NYS PSC projects that we will have 1300 wind towers within the next 8 years, most of them in Western New York. There are currently NO REGULATIONS in New York to protect citizens from the inappropriate siting of these massive towers. SCIDA has the opportunity to show New York how this project can be done right, and we hope they rise to the challenge. Thanks again for your interest in what will be a critical issue for Prattsburgh, Steuben county and all of New York.

Please feel free to contact me should you need any further clarification.

Best regards,

John,
Thank you for an excellent reply.
Cynthia

Subject: Setbacks and Request for Correction

Rob Price
Steuben Courier Advocate

Dear Rob,

It was a pleasure speaking with you this afternoon about the Advocates for Prattsburgh (AFP) presentation to SCIDA on 11/18/04 and we appreciate your covering and writing about the meeting for the Steuben Courier Advocate. As we discussed, I will be sending you a hard copy of the Power Point presentation, in which we mentioned specifics regarding setbacks from the property lines of non-participating landowners. I mentioned this because **AFP did NOT specifically request a blanket 1500' setback from property lines**. What we requested and explained were various needs for setbacks which would adequately address *health, safety, noise and viewshed issues*. The minimum setback requirements are not arbitrary, as the need for setbacks varies with the nature of the problem which needs to be addressed and the siting of the towers. The setbacks are referenced to the **requirements necessary to adequately address specific problems** which will occur if these machines are placed between the homes and properties of non-participating landowners.

One of the most important (and easily regulated) setback is for **high-frequency noise**. We referenced the 10/1/04 letter from the DEC to SCIDA indicating how noise studies should be conducted at the **property lines** of non-participating landowners, when the leaves are off the trees, from the precise location of each tower. I will be sending you this DEC letter in a separate e-mail. As we discussed, Pastor Danley's house in Fenner is over 2000' away from the nearest tower, and the noise problem at times, at her location is quite bad. Considering this and other information and data we have, AFP would NEVER request a noise setback of only 1500'. The background noise level at some of the property lines near proposed tower locations is in the range of 34-36dB(A). I can tell you this: where I have my house, it's QUIET. Because of the low background noise, it is more probable that actual noise setbacks consistent with the 10/1/04 DEC guidelines would be in the range of 2200-3000', dependent of course, upon local conditions.

We also mentioned setbacks of at least **1 mile for low frequency noise**, the sub-audible noise which can make people sick. (Please see the attached article. I can provide more information should you need it.) For example, the city of Riverside, CA has an ordinance requiring a 2 mile setback for wind towers, unless the manufacturer can prove that the machine model in question will not produce any impulsive, tonal noise in the low frequency range. While AFP is potentially willing to accept a manufacturer's guarantee as mitigation for low frequency noise, we will first need to get the straight story from GE Wind Energy in Tahachapi, CA. As you and I discussed, when pressed for specifications the manufacturer has been non-responsive, claiming that virtually all technical information is "proprietary". Then they refer us to a cheerful person in Marketing, who thus far has acknowledged no problems resulting from the operations of these wind towers under any circumstances whatsoever. This has not been reassuring.

Shadow flicker - reflections of the sun off the blades - can turn each rotor into a giant strobe generator. Shadow flicker can cause seizures and migraines in susceptible individuals. The flicker effect occurs primarily during the first 60-90 minutes after sunrise and the first 60-90 minutes

ELLENBURG PACKAGE

Health, hazard, and quality of life near wind power installations

How close is too close?

Nina Pierpont, MD, PhD*

Malone (New York, USA) Telegram,

March 2, 2005, p. 5

Falling over

A nacelle (generator and gearbox) weighing up to 60 tons atop a 265 ft. metal tower, equipped with 135 ft. blades, is a significant hazard to people, livestock, buildings, and traffic within a radius equal to the height of the structure (400 ft) and beyond. In Germany in 2003, in high storm winds, the brakes on a wind turbine failed and the blades spun out of control. A blade struck the tower and the entire nacelle flew off the tower. The blades and other parts landed as far as 1650 ft (0.31 mile) from the base of the tower.¹ (Note that all turbines discussed in this article are "upwind," three-bladed, industrial-sized turbines. "Downwind" turbines have not been built since the 1980's.) Given the date, this turbine was probably smaller than the ones proposed for current construction, and thus could not throw pieces as far. This distance is nearly identical to calculations of ice throw from turbines with 100 ft blades rotating 20 times per minute (1680 ft).²

Fires

Most fires in wind turbines are started by lightning and fueled by up to 200 gallons of hydraulic oil in the nacelle. Fire-fighting at 265 ft (26 stories) may not be possible with the equipment of a rural town. A fire may leave wind turbine controls malfunctioning until the equipment in the nacelle is repaired or replaced, making it more susceptible to the kind of accident described above.

Lightning and power surges

Wind turbines themselves cause irregularities in the power supply as wind speed changes. Within the power grid, supply and demand must always be balanced; there is no storage of electricity on this scale. When the wind dies, there is less power (brown-out) until a coal- or gas-powered plant at some distance from the wind installation fires up to increase production. When the wind gusts, there are power surges. Residents living near a new wind turbine installation in

Meyersdale, PA, which came on-line in December 2003, have had to replace stove elements and small appliances due to power surges which started at that time. Residents of Lincoln Township, WI, near a wind installation noticed an increase in lightning strikes in their area after the turbines went on-line in June 1999. Two computers protected by surge protectors and a TV set, all in different houses, were simultaneously "fried" one evening when lightning struck a nearby wind turbine tower.³

Flicker

When turning with the sun behind them, turbine blades cast moving shadows across the landscape and houses, described as a strobe effect within houses, which can be difficult to block out. Some people lose their balance or become nauseated from seeing the movement. As with car or sea sickness, this is because the three organs of position perception (the inner ear, eyes, and stretch receptors in muscles and joints) are not agreeing with each other: the eyes say there is movement, while the ears and stretch receptors do not. People with a personal or family history of migraine, or migraine-associated phenomena such as ear sickness or vertigo, are more susceptible to these effects. The strobe effect can also provoke seizures in people with epilepsy.

In Lincoln Township, WI, two years after installation, 33% of residents 800 ft to ¼ mile from the turbines found shadows from the blades to be a problem, 40% ¼ to ½ mile away, 18% ½ to 1 mile away, and 3% 1 to 2 miles away (230 people sampled).

Noise

In the same survey in Lincoln Township in 2001, 44% of residents 800 ft to ¼ mile from the turbines found noise to be a problem in their households, 52% ¼ to ½ mile away, 32% ½ to 1 mile away, and 4% 1 to 2 miles away (229 people sampled). Under certain conditions the turbines could be heard up to 2 miles away. These numbers correspond well to measurements made by a sound engineer near a more recent 30 MW, 17 turbine installation on the Dutch-German border, where residents living 500 m (1640 ft, or 0.31 mile) and more from the turbines were reacting strongly to the noise, and residents up to 1900 m (1.2 miles) away expressed annoyance. The engineer found that measured sound levels were higher than predicted by standard models because of differences in daytime and nighttime wind patterns, and that annoyance was increased by the impulsive nature or rhythmic thumping of the sound, a pattern found at a distance from the turbines (documented at 1500 m, or 0.9 mile) but not immediately under or among the turbines.⁴ This was described as a "low pitched thumping sound."

Noise levels sufficient to prevent or interrupt sleep, even with windows closed, are reported in dwellings close to wind power installations in all surveys. Low frequency sound, defined as 10-200 Hz, travels farther and comes through walls and around obstacles because of its long wavelength; sounds in the range of 25-150 Hz have wavelengths similar to room dimensions, and can reverberate in rooms. Low frequency sound is especially bothersome, according to the World Health Organization:⁵

"Low frequency noise, for example from ventilation systems, can disturb rest and sleep even at low sound levels."

"For noise with a large proportion of low frequency sounds a still lower [measurement] guideline (than 30dBA) is recommended." [This means 30 dB total sound pressure using an "A" filter.]

"When prominent low frequency components are present, noise measures based on A-weighting are inappropriate." [An "A" filter, which filters out low-frequency sounds, is standard in loudness measurement.]

"Since A-weighting underestimates the sound pressure level of noise with low frequency components, a better assessment of health effects would be to use C-weighting." [A "C" filter filters out less of the low-frequency sound.]

"It should be noted that a large proportion of low frequency components in a noise may increase considerably the adverse effects on health."

In other words, the World Health Organization recommends that threshold standards for noise in communities be set lower than 30dB (as measured with the standard "A" filter) whenever the noise has a substantial low-pitched component - as it does from wind turbines. Again, this is because low-pitched noise is more disturbing and has a greater impact on health at low levels than higher-pitched noise. When measuring such noise, a "C" filter will give a more accurate reading of loudness by including more of the low-frequency sounds.

Dr. Amanda Harry, a British physician, found (near a 16-turbine installation in 2003) that 13 out of 14 people surveyed reported an increase in headaches, and 10 reported sleep problems and anxiety. Other symptoms included migraine, nausea, dizziness, palpitations, stress, and depression.⁶

Noise itself can induce dizziness and loss of balance in people with a previous history of noise-induced hearing loss, since, when people damage their hearing through too much exposure to loud (e.g., machine) noise, the balance organs in the inner ear may also be damaged. This is known as the Tullio phenomenon.

Dizziness (specifically, vertigo) and anxiety are neurologically linked phenomena.⁷ Hence the anxiety and depression seen in association with other symptoms near wind installations are not a neurotic response to symptoms, but rather a neurologically linked response to the balance disturbances people experience from shadow flicker or low-frequency noise. Sleep deprivation, by the way, also causes anxiety and depression.

Older people, who often sleep less soundly, are more likely to have their sleep disturbed by turbine noise. They may also suffer more disturbances in equilibrium near turbines because of age-related problems with the function of the inner ear (e.g., dizziness and tinnitus: ringing in the ears) or from the nerves or parts of the brain receiving signals from the inner ear. It is noteworthy that among healthy people age 57 to 91, 5% have chronic dizziness, and 24% tinnitus.⁸

Setback

Based on these health effects and hazards, turbines should not be placed within 1700 feet of any road or dwelling. Those living within 1/2 mile (2640 ft) should be apprised that they are likely to experience very bothersome levels of noise and flicker, which continue (though to a lesser degree) to a mile or more from the turbines. At 2 miles, noise is sometimes heard, but few people are bothered. In Lincoln Township, WI, after two years with the turbines, 73% of people said they would not consider buying or building a house within a mile of the turbines, and 23% wished to be at least 2 miles away (212 people sampled).

It is significant that each of these setbacks (the first for hazard of falling objects, the second for noise) is supported by two unrelated pieces of data yielding the same result. For noise, the data from two wind installations of different ages in different countries, one by resident survey and the other an engineer's measurements, yield the same distance at which noise stops being bothersome: at something greater than 1-1.2 miles. Thus the age or specific type of equipment is not relevant to the noise issue, and specific measurements, properly done, support what neighbors of wind installations are saying.

In conclusion, based on these data, wind turbines should not be built within 1.5 miles of people's homes. Let it be understood, however, that there will still be health and life quality problems caused by wind turbines beyond this radius. People living 1.5 to 3 miles from a proposed turbine site should be notified of potential health and life quality effects, and for this they should be appropriately compensated.

Effects of the wind profile at night on wind turbine sound

G.P. van den Berg*

Science Shop for Physics, University of Groningen, Nijenborgh 4, 9747 AG Groningen, Netherlands

Received 22 January 2003; accepted 22 September 2003

Abstract

Since the start of the operation of a 30 MW, 17 turbine wind park, residents living 500 m and more from the park have reacted strongly to the noise; residents up to 1900 m distance expressed annoyance. To assess actual sound immersion, long term measurements (a total of over 400 night hours in 4 months) have been performed at 400 and 1500 m from the park. In the original sound assessment a fixed relation between wind speed at reference height (10 m) and hub height (98 m) had been used. However, measurements show that the wind speed at hub height at night is up to 2.6 times higher than expected, causing a higher rotational speed of the wind turbines and consequently up to 15 dB higher sound levels, relative to the same reference wind speed in daytime. Moreover, especially at high rotational speeds the turbines produce a 'thumping', impulsive sound, increasing annoyance further. It is concluded that prediction of noise immersion at night from (tall) wind turbines is underestimated when measurement data are used (implicitly) assuming a wind profile valid in daytime.

1. Introduction

In Germany several wind turbine parks have been and are being established in sparsely populated areas near the Dutch border. One of these is the Rhule Wind Park in northwestern Germany with seventeen 1.8 MW turbines of 98 m hub height and with 3-blade propellers of 35 m wing length. The turbines have a variable speed increasing with wind speed, starting with 10 r.p.m. (revolutions per minute) at a wind speed of 2.5 m/s at hub height up to 22 r.p.m. at wind speeds of 12 m/s and over.

At the Dutch side of the border is a residential area along the Oude Laan and Veendijk (see Fig. 1) in De Lether: countryside dwellings surrounded by trees and agricultural fields. The dwelling nearest to the wind park is some 500 m west of the nearest wind turbine (W 16).

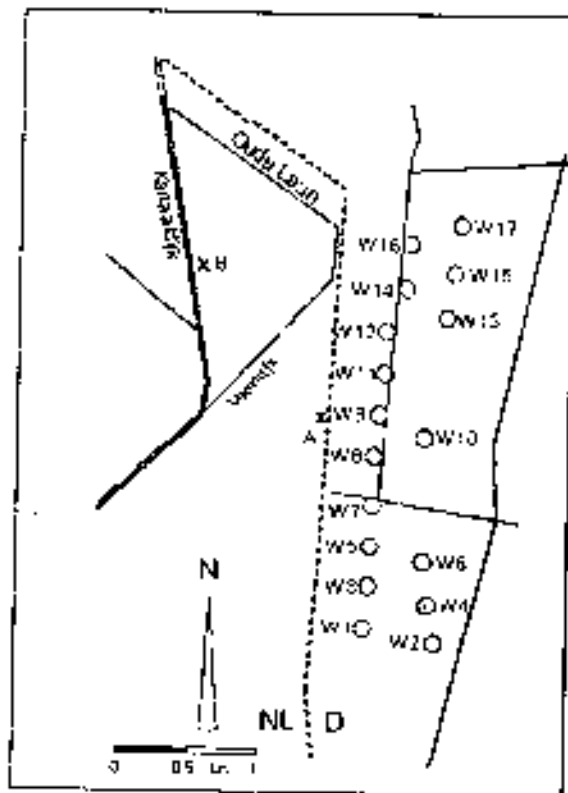

Fig. 1. Location of wind turbines ($W_{i,j}$) and emission measurements (A and B) near the Dutch/German (NL/D) border.

According to a German noise assessment study a maximum immission level of 43 dB(A) was expected, 2 dB below the applied German noise limit. According to a Dutch consultancy immission levels would comply with Dutch (wind speed dependent) noise limits.

After the park was put into operation residents made complaints about the noise, especially at (late) evening and night-time. The residents, united in a neighbourhood group, could not persuade the German operator to put in place mitigation measures or to carry out an investigation of the noise problem and brought the case to court. The Science Shop for Physics had just released a report explaining a possible discrepancy between the calculated and the actual sound immission levels of the wind turbines because of changes in wind profile, and was asked to investigate the consequences of this discrepancy by sound measurements. Although at first the operator agreed to supply measurement data from the wind turbines (such as power output, rotation speed, axle direction), this was withdrawn after the measurements had started. All relevant data therefore had to be supplied or deduced from the author's own measurements.

2. Noise impact assessment

In the Netherlands and Germany noise impact on dwellings near a wind turbine or wind turbine park is calculated with a sound propagation model. Wind turbine sound power levels $L_{w,i}$ are used

as input for the model, based on measured or estimated data. In Germany a single 'maximum' sound power level (at 95% of maximum electric power) is used to assess sound impact. In the Netherlands sound power levels related to wind speeds at 10 m height are used; the resulting sound immission levels are compared to wind speed-dependent noise limits. Implicitly this assessment is based on measurements in daytime and does not take into account atmospheric conditions affecting the wind profile, especially at night.

In the Netherlands a national calculation model is used [1] to assess noise impact, as is the case in Germany [2]. According to Kerckers [3] there are, at least in the case of these wind turbines, no significant differences between both models.

In both sound propagation models the sound immission level L_{imm} at a specific observation point is a summation over j sound power octave band levels L_{Wj} of k sources (turbines), reduced with attenuation factors $D_{j,k}$:

$$L_{imm} = 10 \log \left[\sum_j \sum_k 10^{(L_{Wj} - D_{j,k})/10} \right], \quad (1)$$

where L_{Wj} , assumed to be identical for all k turbines, is a function of rotational speed. $D_{j,k}$ is the attenuation due to geometrical spreading (D_{geo}), air absorption (D_{air}) and ground absorption (D_{ground}): $D_{j,k} = D_{geo} + D_{air} + D_{ground}$.

Eq. (1) is valid for a downwind situation. For long-term assessment purposes a meteorological correction factor is applied to (1) to account for an 'average atmosphere'. When comparing calculated and measured sound immission levels in this study no such meteo-correction is applied.

3. Wind turbines noise perception

There is a distinct audible difference between the night and daytime wind turbine sound at some distance from the turbines. On a summer's day in a moderate or even strong wind the turbines may only be heard within a few hundred metres and one might wonder why residents should complain of the sound produced by the wind park. However, on quiet nights the wind park can be heard at distances of up to several kilometres when the turbines rotate at high speed. On these nights, certainly at distances between 500 and 1000 m from the wind park, one can hear a low pitched thumping sound with a repetition rate of about once a second (coinciding with the frequency of blades passing a turbine mast), not unlike distant pile driving, superimposed on a constant broadband 'noisy' sound. A resident living at 1.5 km from the wind park describes the sound as 'an endless train'. In daytime these pulses are not clearly audible and the sound is less intrusive or even inaudible (especially in strong winds because of the then high ambient sound level).

In the wind park the turbines are audible for most of the (day and night) time, but the thumping is not evident, although a 'swishing' sound—a regular variation in sound level caused by the pressure variation when a blade passes a turbine mast—is readily discernible. Sometimes a rumbling sound can be heard, but it is difficult to assign it, by ear, to a specific turbine or to assess its direction.

4. Stability-dependent wind profiles

Usually a fixed relation is assumed between the wind speed v_h at height h and the wind speed v_{ref} at a reference height h_{ref} (usually 10 m), which is the widely used logarithmic wind profile with surface roughness z as the only parameter. See for example the international recommendations for wind turbine noise emission measurements [4,5]. For height h the wind speed v_h is calculated as follows:

$$v_h = v_{ref} \log(h/z) / \log(h_{ref}/z). \quad (2)$$

This equation is an approximation of the wind profile in the turbulent boundary layer of a neutral atmosphere, when the air is mixed by turbulence resulting from friction with the surface of the earth. During daytime thermal turbulence is added, especially when the heating of the earth surface by the sun is significant. At night-time a neutral atmosphere, characterized by the adiabatic temperature gradient, occurs under heavy cloud and/or at relatively high wind speeds. When there is some clear sky and in the absence of strong winds the atmosphere becomes stable because of radiative cooling of the surface: the wind profile changes and can no longer be adequately described by Eq. (2). The effect of the change to a stable atmosphere is that, relative to a given wind speed at 10 m height in daytime, at night there is a higher wind speed at hub height and thus a higher turbine sound power level; also there is a lower wind speed below 10 m and thus less wind-induced sound in vegetation. According to measurements by Holtslag [6] in a non-neutral atmosphere (either stable or unstable) a correction must be added to the logarithmic terms in the wind profile according to Eq. (2):

$$v_h = v_{ref} [\log(h/z) - \Psi_{\pi}] / [\log(h_{ref}/z) - \Psi_{\pi}], \quad (3)$$

where $\Psi_{\pi} = \Psi_{\pi}(h/L)$ is a rather elaborate function of height h and Monin Obukhov length L . L is a stability measure and is positive for a stable, negative for an unstable atmosphere; for a neutral atmosphere L is a large number, either positive or negative. For calculations of sound propagation in the atmosphere Kühner [7] proposes a simple equation used in the German Air Quality Guideline "TA-Luft" [8]:

$$v_h = v_{ref} (h/h_{ref})^m, \quad (4)$$

where m is a number that depends on stability.

Stability can be categorized in Pasquill classes that depend on observations of wind speed and cloud cover (see, e.g. Ref. [9]). They are usually referred to as classes A (very unstable) through F (very stable). In "TA-Luft" a closely related classification is given (again closely related, according to Kühner [7], to the international Turner classification). An overview of stability classes with the appropriate value of m is given in Table 1. In Fig. 2 wind profiles are given as measured by Holtslag [6], as well as wind profiles according to Eqs. (2) and (4).

According to long-term data from Eelde and Leeuwarden [10], two meteorological measurement sites of the KNMI (Royal Dutch Meteorological Institute) in the northern part of the Netherlands, a stable atmosphere (Pasquill classes E and F) at night occurs for a considerable proportion of night-time: 34% and 32%, respectively.

According to Eq. (2) the ratio of wind speed at hub height (98 m) to wind speed at reference height, over land with low vegetation ($z = 3$ cm), would be $f_{log} = v_{98}/v_{10} = 1.4$. According to

Table 1
Stability classes and factor σ

Pasquill class	Name	Comparable stability class "TA-Luft" [8]	σ
A	Very unstable	V	0.09
B	Moderately unstable	IV	0.20
C	Neutral	III2	0.22
D	Slightly stable	III1	0.26
E	Moderately stable	II	0.37
F	(Very) stable	I	0.41

Fig. 2. Measured wind profiles (thin lines, [6]) and wind profile according to TA-Luft (dotted line, [8]) in a stable atmosphere, and wind profile according to logarithmic model of formula 2 with $z_0 = 3$ cm (bold line).

Eq. (4) and Table 1 this ratio would be 1.2 in a very unstable atmosphere and $f_{limit} = 2.5 = 1.8f_{log}$ in a (very) stable atmosphere.

The fact that wind speeds at 10 m height may not be a good, unique predictor for hub height wind speeds has been put forward by Rudolph [11]. He concluded from measurements that wind speed at 10 m height is not a good measure for wind turbine sound power: according to his measurements near a 58 m hub height wind turbine at night the turbine sound level was 5 dB higher than expected. This conclusion was not followed by a more thorough investigation.

The question addressed in this study is: what is the influence of the change in wind profile on the sound emission near (tall) wind turbines?

5. Measurement method

Sound emission measurements were made over 1435 hours, of which 417 hours were at night, within four months at two consecutive locations with an unmanned Sound and Weather

Measurement System (SWMS) consisting of a type 1 sound level meter with a microphone at 4.5 m height with a 9 cm diameter foam wind shield, and a wind meter at 10 m as well as at 2 m height. Every second, wind speed and wind direction (at 10 and 2 m height) and the A-weighted sound level were measured, the measured data are stored as statistical distributions over 5 min intervals. From these distributions all necessary wind data and sound levels can be calculated, such as average wind speed, median wind direction or equivalent sound level and any percentile (steps of 5%) wind speed, wind direction or sound level, in intervals of 5 min or multiples thereof.

Also complementary measurements were done with logging types 1 and 2 sound level meters and a type 1 spectrum analyzer to measure immission sound levels in the residential area over limited periods (12), not reported here), and emission levels near the wind turbines. Emission levels were measured according to international standards [4,5], but for practical purposes the method could not be adhered to in detail: with respect to the recommended values a smaller reflecting board was used for the microphone (30 × 44 cm² instead of a 1 m diameter circular board) and a smaller distance to the turbine (equal to tower height instead of tower height + blade length); reasons for this are given in a separate paper [13]. Also it was not possible to carry out emission measurements with only one turbine in operation.

6. Results: sound emission

Emission levels L_{Nv} measured very close to the centre of a horizontal, flat board at a distance R from a turbine hub can be converted to a turbine sound power level L_W [4,5]:

$$L_W = L_{Nv} - 6 + 10 \log(4\pi R^2). \quad (5)$$

From earlier measurements [3] a wind speed dependence of L_W was established as given in Table 2. As explained above, the wind speed at 10 m height is not considered a reliable single measure for the turbine sound power. Rotational speed is a better measure.

Emission levels have been measured, typically for 5 min per measurement, at nine turbines on seven different days with different wind conditions. The results are plotted in Fig. 3, the sound power level is plotted as a function of rotational speed N . N is proportional to wind speed at hub height and could be determined by counting, typically during 1 min, blades passing the turbine mast. This counting procedure is not very accurate (accuracy per measurement is ≈ 2 counts, corresponding to 2/3 r.p.m.) and is probably the dominant reason for the spread in Fig. 3. The best logarithmic fit to the data points in Fig. 3 is

$$L_W = 67.1 \log(N) + 15.4 \text{ dB(A)} \quad (6)$$

with a correlation coefficient of 0.98. The standard deviation of measurement values with respect to this fit is 1.0 dB.

Table 2
Sound power level of wind turbines [3]

Wind speed v_{10}	m/s	5	6	7	8	9	10
Sound power level L_W	dB(A)	94	96	98	101	102	103

At the specification extremes of 10 and 22 r.p.m. the (individual) wind turbine sound power level L_{WP} is 82.8 and 105.7 dB(A), respectively

In Table 3 earlier measurement results [3] are given for the octave band sound power spectrum. Also in Table 3 the results of this study are given: the logarithmic average of four different spectra at different rotational speeds. In all cases spectra are scaled, with Eq. (6), to the same sound power level of 103 dB(A).

To calculate sound immission levels at a specific rotational speed (or vice versa) the sound power level given in Eq. (6), and the spectral form in Table 3 ('this study') have been used.

7. Results: sound immission

The sound immission level has been measured with the unmanned SWMS on two locations. Between May 13 and June 22, 2002 it was placed amidst open fields with barren earth and later low vegetation 400 m west of the westernmost row of wind turbines (location A, see Fig. 1). This site was a few metres west of the Dutch–German border, visible as a ditch and a 1.5–2 m high dike. Between June 22 and September 13, 2002 the SWMS was placed on a lawn near a dwelling 1500 m

Fig. 3. Measured wind turbine sound power level L_{WP} as a function of turbine rotational speed N .

Table 3
Octave band spectra of wind turbines at $L_{WP} = 103$ dB(A)

Frequency	Hz	63	125	250	500	1000	2000	4000	L_{WP}
This study	dB(A)	82	92	94	98	98	93	88	103
[7]	dB(A)	85	91	95	98	98	92	83	103

west of the westernmost row (location B), with both low and tall trees in the vicinity. On both locations there were no reflections of turbine sound towards the microphone, except via the ground, and no objects (such as trees) between the turbines and the microphone. Apart from possible wind induced sound in vegetation relevant sound sources are traffic on rather quiet roads, agricultural activities, and birds. As, because of the trees, the correct (potential) wind speed and direction could not be measured on location B, wind measurement data provided by the KNMI were used from their Nieuw Beerta site 10 km to the north. These data fitted well with the measurements on location A.

At times when the wind turbine sound is dominant, the sound level is relatively constant within 5 min intervals. In Fig. 4 this is demonstrated for two nights. Thus measurement intervals with dominant turbine sound could be selected with a criterion based on a low variation in sound level, $L_5 - L_{95} \leq 4$ dB, where L_5 and L_{95} are 5 and 95 percentile sound level. In a normal (Gaussian) distribution this would equal $\sigma \leq 1.2$ dB, with σ the standard deviation.

On location A, 400 m from the nearest turbine, the total measurement time was 371 h. For 25% of this time the wind turbine sound was dominant, predominantly at night (72% of all 105 nightly hours) and hardly during daytime (4% of 191 h) (see Table 4).

At location B, 1500 m from the nearest turbine, these percentages were almost halved, but the turbine sound remained dominant for over one-third of the time at night (38% of 312 h). The trend in percentages agrees with complaints mostly concerning noise in the (late) evening and at night and their being more strongly expressed by residents closer to the wind park.

In Fig. 5 the selected (i.e., with dominant wind turbine sound) 5 min equivalent immission sound levels $L_{eq,5 \text{ min}}$ are plotted as a function of wind direction (left) and of wind speed (right) at 10 m height, for both location A (above) and B (below). It is not clear why the KNMI wind speed data (used for location B) cluster around integer values of the wind speed.

Also the wind speed at 10 and 2 m height at location A are plotted (in 5A and 5B, respectively), and the local wind speed (influenced by trees) at 10 m at location B (5C). The immission level data points are separated in two classes where the atmosphere was stable or neutral, according to

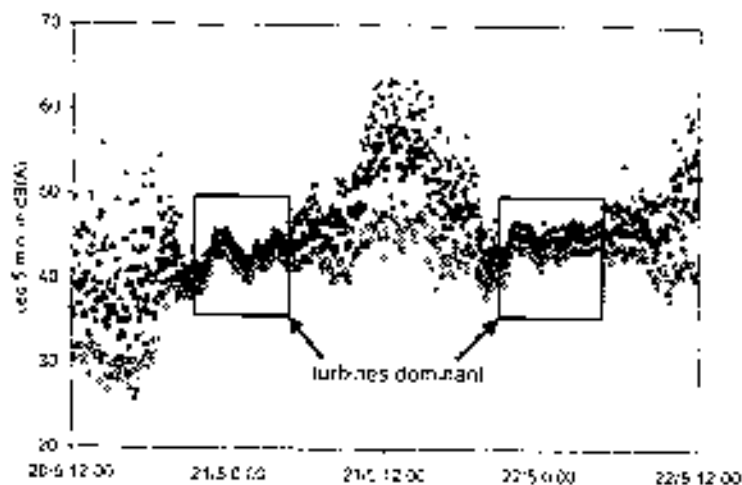

Fig. 4. 48 h registration of immission level ($L_5 - \Delta$; $L_{50} - \square$; $L_{95} - \circ$) per 5 min at location A; turbines are considered the dominant sound source if $L_5 - L_{95} \leq 4$ dB.

Table 4
Total measurement time in hours and selected time with dominant wind turbine sound

Location	Total time	Night 21:00–6:00	Evening 19:00–23:00	Day 6:00–19:00
A: Total	371	105	75	191
A: Selected	92	26	9	7
	25%	22%	12%	4%
B: Total	1064	312	383	369
B: Selected	136	119	13	4
	13%	38%	7%	0.7%

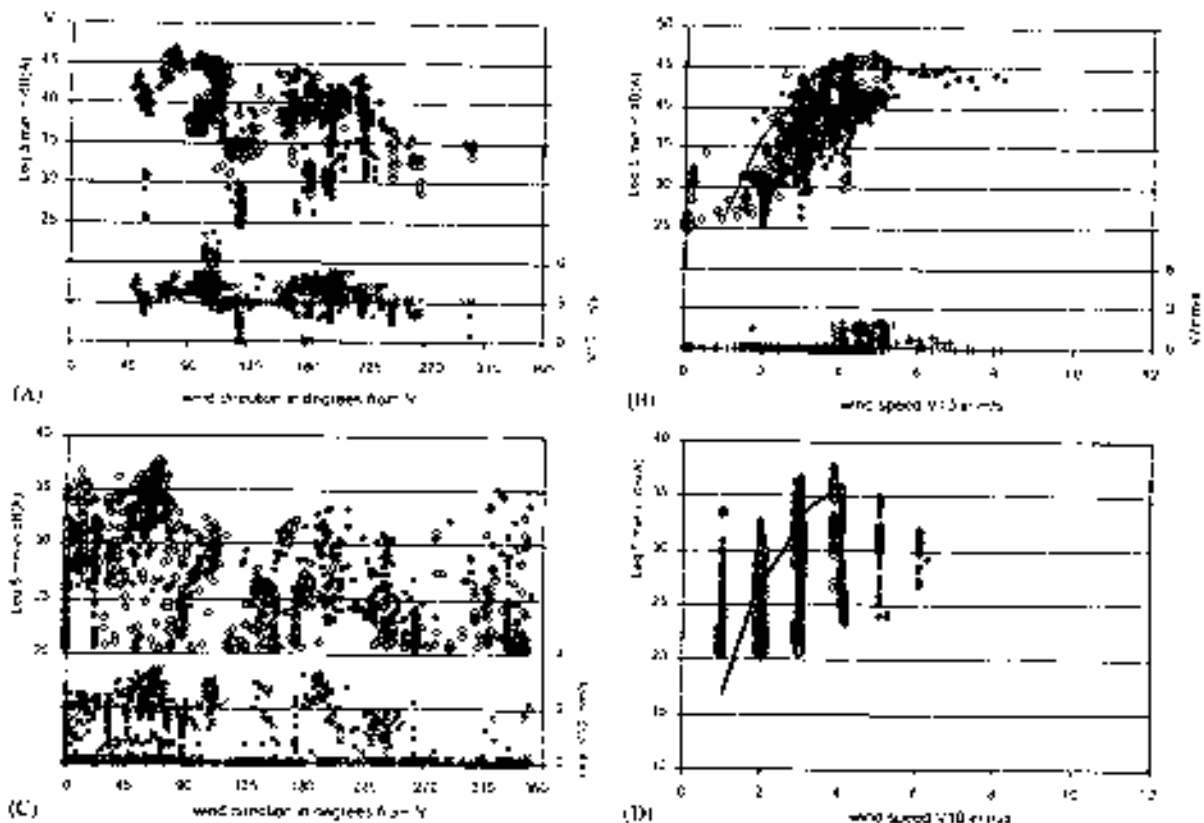

Fig. 5. Measured sound levels $L_{w,d,5m,1}$ at locations A (above) and B (below) as a function of median wind direction (left) and average wind speed (right) at reference height (10 m), separated in classes where the atmosphere at Eelde was observed as stable (\diamond) or neutral (\bullet). Also plotted are expected sound levels according to logarithmic wind profile and wind speed at reference height (grey lines in B and D), and at a 2.6 higher wind speed (black lines in B and D). Figures A, B and C also contain the wind speed v_{10} (A), v_2 (B), and the local v_{10} (C) (disturbed by trees, respectively).

observations of wind speed and cloud cover at Eelde. Eelde is the nearest KNMI site for these observations, but it is 40 km to the west, so not all observations will be valid for the area of the study.

In Fig. 5B a grey line is plotted connecting calculated sound levels with sound power levels according to Table 2 (the lowest value at 2.5 m/s is extrapolated [12]), implicitly assuming a fixed logarithmic wind profile according to Eq. (2). If this line is compressed in the direction of the abscissa with a factor 2.6, the result is a (black) line coinciding with the highest 1-h values ($L_{eq,1h}$) at each wind speed. Apparently, at these immission levels, the wind speed is 2.6 times higher than expected. In Fig. 6 this is given in more detail: all 5 min measurement periods that satisfied the L_5-L_{95} -criterion, with at least 4 periods per hour, were taken together in consecutive hourly periods and the resulting $L_{eq,T}$ ($T = 20\text{--}60$ min) was calculated. These 83 L_{eq} -values are plotted against the average wind speed v_{10} over the same time T . Also plotted in Fig. 6 are: the expected immission levels calculated from (1), implicitly assuming a logarithmic wind profile according to (2), so $f_{log} = 1.4$; the immission levels assuming a stable wind profile (4) with $m = 0.41$, so $f_{stable} = 2.5 = 1.8 \cdot f_{log}$; the maximum immission levels assuming $f_{max} = 3.7 = 2.6 \cdot f_{log}$, in agreement with a wind profile (4) with $m = 0.57$. The best fit of all data points ($L_{eq,T}$) in Fig. 6 with $1 < v_{10} < 5.5$ m/s is $L_{eq,T} = 32 \cdot \log(v_{10}) + 22$ dB (correlation coefficient 0.80); this fit agrees within 0.5 dB with the expected level according to the stable wind profile. The best fit of all 5 min data-points in Fig. 5B yields the same result.

Thus on location A the highest one hour averaged wind speeds at night are 2.6 times the expected values according to the logarithmic wind profile in Eq. (2). As a consequence, sound levels at (during night-time) frequently occurring wind speeds of 3 and 4 m/s are up to 15 dB higher than expected, 15 dB being the vertical distance between the expected and highest 1-h immission levels at 3–4 m/s (upper and lower lines in Figs. 5B and 6).

The same lines as in 5B, but valid for location B, are plotted in Fig. 5D; immission levels here exceed the calculated levels, even if calculated on the basis of a 2.6 higher wind speed at hub height. This is the result of shortcomings of the calculation model for long distances, at least for

Fig. 6. Measured sound levels $L_{eq,T}$ ($T = 20\text{--}60$ min) at location A with best fit, and expected sound levels according to a logarithmic wind profile ($v_{95}/v_{10} = f_{log} = 1.4$, dotted line), a stable wind profile ($v_{95}/v_{10} = 1.8 \cdot f_{log}$, thick grey line) and maximum wind speed ratio ($v_{95}/v_{10} = 2.6 \cdot f_{log}$, thin line).

night-time conditions; from the long-term measurements at location B and short term (one night) at other locations ([12], not reproduced here) it follows that sound immission levels calculated according to the standard model used in the Netherlands [1], underestimate measured levels at night with ca. 1 dB at distances of 550–1000 m increasing to about 3 dB at distances up to 1900 m.

As is clear from the wind speed at 2 m height plotted in Fig. 5B, there is only a very light wind near the ground even when the turbines rotate at high power. This implies that in a quiet area with low vegetation the ambient sound level may be very low. The contrast between the turbine sound and the ambient sound is therefore higher at night than during the daytime.

Although at most times the wind turbine sound dominates the sound levels in Fig. 5, it is possible that at low sound levels, i.e., at low rotational speeds and low wind speeds, the L_5 L_{95} -criterion is met while the sound level is not entirely determined by the wind turbines. This is certainly the case at levels close to 20 dB(A), the sound level meter noise floor.

The long-term night-time ambient background level, expressed as the 95-percentile (L_{95}) of all measured night-time sound levels on location B, was 23 dB(A) at 3 m/s (v_{10}) and increasing with $3.3 \text{ dB}/(\text{m s}^{-1})$ up to $v_{10} = 8 \text{ m/s}$ [12]. Comparing this predominantly non-turbine background level with the sound levels in Figs. 5B and D, it is clear that the lowest sound levels may not be determined by the wind turbines, but by other ambient sounds (and instrument noise). This wind speed dependent, non-turbine background sound level L_{95} is, however, insignificant with respect to the highest measured levels. Thus, the high sound levels do not include a significant amount of ambient sound not coming from the wind turbines. This has also been verified on a number of evenings and nights by personal observation.

8. Comparison of emission and immission sound levels

From the 30 measurements of the equivalent sound level $L_{eq,T}$ (with T typically 5 min) measured at distance R from the turbine hub (R typically $100\sqrt{2}$ m), a relation between sound power level L_{WP} and rotational speed N of a turbine could be determined; see Eq. (6).

This relation can be compared with the measured immission sound level $L_{i,T}$ ($T = 5$ min) at location A, 400 m from the wind park (closest turbine), in 22 cases where the rotational speed was known. These measurements were taken at different times to the emission measurements. The best logarithmic fit for the data points of the immission sound level L_{imm} as a function of rotational speed N is

$$L_{imm} = 57.6 \log(N) + 30.6 \text{ dB(A)} \quad (7)$$

with a correlation coefficient of 0.92 and a standard deviation of 1.5 dB. Both relations from Eqs. (6) and (7) and the data points are given in Fig. 7. The difference between both relations is $L_{WP} - L_{imm} = 9.5 \log(N) + 46.0 \text{ dB}$. For the range 14–20 r.p.m., where both series have data points, the average difference is 57.9 dB, the maximum deviation from this average is 0.8 dB (14 r.p.m.: 57.1 dB(A); 20 r.p.m.: 58.6 dB(A); see lower part of Fig. 7). It can be shown by calculation that about half of this deviation can be explained by the variation of sound power spectrum with increasing speed N .

The sound immission level can be calculated using Eq. (1). For location A, assuming all turbines have the same sound power L_{WP} , this leads to $L_{WP} - L_{imm} = 58.0 \text{ dB}$. This is independent

Fig. 7. Turbine sound power levels L_w measured near wind turbines (●) and immission levels L_{min} measured at 400 m from wind park (○) averages differ 57.9 dB, (below) increase of difference $L_w - L_{min}$ with rotational speed

of sound power level or rotational speed, as it is calculated with a constant spectrum averaged over several turbine conditions, i.e., speeds. The measured difference (57.9 dB) matches very closely the calculated difference (58.0 dB).

The variation in sound immission level at a specific wind speed v_{10} in Figs. 5B and D is thus seen to correspond to a variation in rotational speed N , which in turn is related to a variation in wind speed at hub height, not to a variation in v_{10} . At location A, N can be calculated from the measured immission level with the help of Eq. (7) or its inverse form $N = 3.4 \times 10^{L_{min}/57.6}$.

9. Effect of atmospheric stability

In Fig. 5 measurement data have been separated into two sets according to atmospheric stability in Pasquill classes, supplied by KNMI from their measurement site Felde, 40 km to the west of our measurement site. Although the degree of stability will not always be the same for Felde and our measurement location, the locations will correlate to a high degree in view of the relatively small distance between them. For night-time conditions 'stable' refers to Pasquill classes E and F (lightly to very stable) and corresponds to $V_{10} \leq 5$ m/s and cloud coverage $C \leq 50\%$ or $V_{10} \leq 3.5$ m/s and $C \leq 75\%$, 'neutral' (class D) corresponding to all other situations. Although from Fig. 5 it is clear that the very highest sound levels at an easterly wind ($\approx 80^\circ$) do indeed occur

in stable conditions, it is also clear that in neutral conditions too the sound level is higher than expected for most of the time, the expected values corresponding to the grey lines in Figs. 5B and D, derived from daytime conditions. According to this study the sound production, and thus wind speed, at 100 m height is often higher than expected at night, in a stable, but also in a neutral atmosphere. On the other hand, even in stable conditions sound levels may be lower than expected (i.e., below the grey lines), although this rarely occurs. It may be concluded from these measurements that a logarithmic wind profile based only on surface roughness does not apply to the night-time atmosphere in our measurements, not in a stable atmosphere and not always in a neutral atmosphere.

10. Impulsive sound

At night the sound from the wind park contains repetitive pulses, unlike the sound in daytime. According to the long-term auditory observation of residents this pulse-like character or ‘thumping’, is more pronounced and more annoying at high turbine rotational speed. Fig. 8 shows a recording of the sound pressure level every 50 ms over a 180 s period, taken from a DAT-recording on a summer night (June 3, 0:40 h) on a terrace of a dwelling at 750 m west of the westernmost row of wind turbines (this sound includes the reflection on the façade at 2 m). There is a slow variation of the ‘base line’ (minimum levels) probably caused by variations in wind speed and atmospheric sound transmission. There is furthermore a variation in dynamic range: a small difference between subsequent maximum and minimum levels of less than 2 dB is alternated by larger differences. In the lower part of Fig. 8 part of the sequence is amplified and shows at first a somewhat irregular pattern of dynamic range 1–1.5 dB leading to a more regular pattern of a pulse every second with a pulse height of 3–4 or 5–6 dB. This pattern is compatible with a complex of three pulse trains with pulse height of about 1 dB and slightly different repetition frequencies

Fig. 8. Sound pressure level caused by wind turbines per 50 ms near dwelling at 750 m from nearest turbine (including reflection at façade at 2 m) over a 3 min period, part of the sequence is amplified below.

of about 1 Hz. When the pulses are out of phase (around 150 s in Fig. 8), there are only 1 dB variations. When 2 of them are in phase (around 160 s) pulse height is doubled (+ 3 dB), and tripled (+ 5 dB, 170 s) when all three are in phase. The rotational speed of the turbines at the time was 20 r.p.m., so the repetition rate of blades passing a mast was 1 Hz.

The low number of pulse trains, compared to 17 turbines, is compatible with the fact that only a few turbines dominate the sound immission at this location. The calculated immission level is predominantly caused by two wind turbines (numbers 11 and 12; see Fig. 1, contributing 35% of the A-weighted sound energy), less by two others (9 and 14; 21%), so only 4 turbines contribute more than half of the sound immission energy.

A pulse-like character was not expected; e.g., in a recent Dutch report [14] it was stated that wind turbines do not produce impulsive noise. However, when measurements are made at a single turbine, as is usual, no pulses will be audible according to the explanation given above.

11. Annoyance

The immission sound level at location A is for most of the time (at least 72% of night-time hours) higher than expected. At the most frequent night-time wind speeds (v_{10}) of 3 and 4 m/s the sound level is up to 15 dB more than expected. Also at location B, at a considerable distance (1500 m) from the wind park, the immission level is for a considerable amount of time (at least 38% of night-time hours) higher than expected. At location B and at wind speeds of 2–4 m/s the actual sound level is up to 18 dB higher than expected, of which 3 dB are due to limitations of the calculation model, and 15 dB to the underestimate of wind speed at hub height. With these higher sound levels and the impulsive character of the sound more annoyance than predicted is to be expected.

Pedersen et al. [15] have investigated the annoyance around wind turbines in the south of Sweden. Their paper gives preliminary results, and definitive results have yet to be published (personal communication Pedersen). They found highly annoyed residents at (calculated) sound levels as low as 32.5–35 dB(A). This study shows that tall wind turbines may in fact be up to 18 dB noisier than the calculated values suggest. A further increase in annoyance may be expected because of the pulse-like character of the wind turbine noise, especially at high rotational speeds.

12. Conclusions

Sound immission measurements have been made at 400 m (location A) and 1500 m (location B) from the wind park Rhede with 17 tall (98 m hub height), variable speed wind turbines. It is usual in wind turbine noise assessment to calculate immission sound levels assuming wind speeds based on wind speeds v_{10} at reference height (10 m) and a logarithmic wind profile. This study shows that the sound immission level may, at the same wind speed v_{10} at 10 m height, be significantly higher (up to 18 dB) during night-time than in the daytime. Another, 'stable' wind profile predicts a wind speed v_h at hub height 1.8 times higher than expected and agrees excellently with the average measured night-time sound immission levels. Wind speed at hub height may still be higher: at low wind speeds v_{10} up to 4 m/s, the wind speed v_h is at night is up to 2.6 times higher than expected

Thus, the logarithmic wind profile, depending only on surface roughness and not on atmospheric stability, is not a good predictor for wind profiles at night. Especially for tail wind turbines, estimates of the wind regime at hub height based on the wind speed distribution at 10 m, will lead to an underestimate of the immission sound level at night. At low wind speeds ($v_{10} \leq 4$ m/s) the actual sound level will be higher than expected for a significant proportion of time. This is not only the case for a stable atmosphere, but also, to a lesser degree, for a neutral atmosphere.

The change in wind profile at night also results in lower ambient background levels than expected: at night the wind speed near the ground may be lower than expected from the speed at 10 m and a logarithmic wind profile, resulting in low levels of wind induced sound from vegetation. The contrast between wind turbine and ambient sound levels is therefore more pronounced at night.

Measured sound immission levels at 400 m from the nearest wind turbine almost perfectly match (average difference: 0.1 dB) sound levels calculated from measured emission levels near the turbines. From this it may be concluded that both the emission and immission levels could be determined accurately, even though the emission measurements were not quite in agreement with the recommended method. As both levels can be related through a propagation model, it may not be necessary to measure both; the immission measurements can be used to assess immission as well as emission sound levels.

There is, however, a growing discrepancy with distance; at distances of 1–2 km the calculated level may underestimate the measured level by 3 dB. This is most probably a consequence of the fact that the actual (night-time) atmospheric sound transmission is not adequately modelled in the sound transmission model.

At night the turbines cause a low pitched thumping sound superimposed on a broadband 'noisy' sound, the 'thumps' occurring at the rate at which blades pass a turbine tower. It appears that the characteristic, but usually small 'swishing' pulses that can be heard at the rate at which blades pass a turbine tower, coincide because turbines operate nearly synchronously. Two coinciding pulse trains thus give a 3 dB higher pulse level, three a 5 dB higher pulse level. The measured pulse levels and frequencies agree with values expected from nearly synchronous pulse trains generated by a small number of wind turbines.

The number and severity of noise complaints near the wind park are at least in part explained by the two main findings of this study; actual sound levels are considerably higher than predicted, and wind turbines can produce sound with an impulsive character.

The relatively high wind speeds at turbine hub height at night also have a distinct advantage; the electric power output is higher than predicted and benefits the operator of the wind turbine.

Abstract

This review paper examines neurologic bases of links between balance control and anxiety based upon neural circuits that are shared by pathways that regulate autonomic control, vestibulo-autonomic interactions, and anxiety. The core of this circuitry is a parabrachial nucleus network, consisting of the parabrachial nucleus and its reciprocal relationships with the extended cerebral amygdala, nucleus, insular cortex, and hypothalamus. Specifically, the parabrachial nucleus is a site of convergence of vestibulo-information processing and somatic and visceral sensory information processing in pathways that appear to be involved in aversive conditioning, anxiety, and conditioned fear. Monoaminergic influences on these pathways are potential modulators of both effects of vigilance and anxiety on balance control and the development of stress-related panic. This neurologic schema provides a unifying framework for investigating the neurologic bases for comorbidity of balance disorders and anxiety. © 2001 Elsevier Science B.V. All rights reserved.

1. Introduction

The recent explosion of activity in the neurosciences has produced new insights into neural circuitry and neurochemical mechanisms for autonomic control, vestibulo-autonomic interactions, anxiety, and emotional expression. However, the strikingly common features of neurologic linkage models for these phenomena have not been appreciated fully because they have evolved in relative

intellectual isolation in separate segments of the neuroscientific community. The unification of these models provides a richer understanding of the potential neural substrates for the balance-anxiety link.

As in previously published neurobiological models of the balance-anxiety link (Jacobs, Furniss, & Balaban, 1996; Wackyle & Balaban, 1998), this communication begins with the premise that the comorbidity of balance disorders and anxiety disorders is likely to be mediated by shared central neural circuits for control of vestibular processing (Balaban, 1996; Balaban & Porter, 1998; Balaban & Yates, in press), autonomic function (Loewy, 1990), emotional responses (Marissau, 1998; Derryberry & Turkur, 1992; Thayer & Lane, in press), and anxiety (Chaney & Detsch, 1996; Gouldard & Chaney, 1997; Corrigan, Leckowitz, Fyot, & Stein, 1989; Klein, 1993). These ideas are developed in three stages. Firstly, neurologic circuits that subservise balance control on anxiety and other emotions are described. These circuits are centered about a parabrachial nucleus network, which is a site of convergence of vestibular and visceral information processing in pathways that appear to be involved in avoidance conditioning, novelty, and conditioned fear. Secondly, additional neuroenergetic components are described to explain (1) the effects of anxiety and other emotions on balance control and (2) the psychopathology of anxiety and panic disorders in conditions of diminished balance function. Finally, a heuristic overview is provided to illustrate the relationship of the model to symptoms of *Space and Motion Disorders* and *Space and Motion Phobias* (Frumkin & Jacob, this issue).

2. Effects of balance control on autonomic function and emotions (including anxiety)

2.1. *Physiology*

2.1.1. *Sensing and responding to gravity and other accelerations*

The vestibular apparatus in the inner ear is merely one sensory modality that conveys information about the position and movement of the body in space (Balaban, 1999; Balaban & Yates, in press; Stratastadi, 1996). The semicircular canals transduce angular accelerations of the head, while the saccular and utricular transduce linear accelerations of the head, including gravity. Similarly, visual information (e.g., "retinal slip," "optic flow," motion parallax, and vergence-accommodation) convey information about angular and linear head velocity. Cutaneous mechanoreceptors and muscle or joint proprioceptors may also sense gravitational loading of body surfaces and joints. However, since every tissue in the body has mass, gravitational accelerations (the sum of gravity, self-imposed acceleration during movement, and externally imposed accelerations) have the potential to be transduced by other tissues within the body (Balaban, 1999; Balaban & Yates, in press; Stratastadi, 1996).

One underappreciated example of a nonvestibular mechanism is the influence of gravitational acceleration on regional blood distributions in the body, which is sensed by baroreceptor afferents that drive orthostatic responses. Moreover, gravitational acceleration affects the movement of the abdominal viscera within the peritoneal cavity (Bramble & Jenkins, 1991; Campbell, Aspinwall, & Davis, 1978), which is sensed by traction on mesenteries, contact with parietal surfaces in peritoneum and stomach due to pressure on diaphragm (Painal, 1978; Revelante, Reynolds, Brown, & Taylor, 1992). Since the actions of gravity on the viscera will vary with the orientation of the torso with respect to the gravitational vector, a simple change from an upright to a supine posture has significant effects of the forces generated by the viscera. Finally, physiological processes as diverse as pulmonary function (Ollivier, 1977), intracranial pressure control (Korte, 1994), and intracranial pressure control (Keil, McKeev, Skidmore, Hines, & Severs, 1992) appear to be sensitive to changes in gravitational acceleration. Hence, sensory signals from these systems also contain information about gravitational changes, which may be used to sense the incident gravitational acceleration, to generate compensatory responses (e.g., vestibulo-ocular reflexes, vestibulo-spinal reflexes, or orthostatic responses), to maintain a sense of spatial orientation, and to predict changes in acceleration in the future.

2.1.2. *Artibular responses and emotions*

We are all familiar with the acute fear and anxiety that ensues from even momentary departures from implicit assumptions about our relationship to a stable or moving spatial and/or gravitational frame. Suppose that you are stopped at a traffic light on a hillside facing up. In anticipation of the traffic signal changing, a large bus that is alongside your car moves forward slowly, giving you a wide-field optic flow stimulus that you interpret as a backward drift of your car on the hill. You feel an urgent sense of panic as a backward drift depress the brake pedal. This is followed by a sense of relief as you realize that the perceived movement was merely illusory. The strong re-orientation of this scenario to its acute panic attack is apparent. However, the least palpable and other symptoms of fear abate as the context of the stimulus becomes apparent.

The sudden onset of vestibular dysfunction produces a more extreme, longer lasting loss of orientation, but without an appropriate context. The fear associated with accidents of acute vertigo has been noted repeatedly in the medical literature, from the fifth century statement from the *Caelius Atrilius* that patients "suffered violentus timor [fear to move]" (Drabkin, 1954) to more recent observations (Cawthorne, 1945; Pan & McKenzie, 1958; Woakes & Wadden, 1996).

There is, however, a very different pattern of autonomic and emotional responses to prolonged, low-frequency gravitational stimulation: the malaise and sense of disgust that accompanies the condition termed "motion sickness" (Mahn, Stern, Thayer, & Koch, 1996). Two extreme subtypes of "motion sickness" are nausea and vomiting, which are also commonly present in acute vestibular dysfunction. The emotional component of these responses, though,

spindles, Golgi tendon organs, and joint receptors). The third category, interoceptive sensations, respond to adequate stimuli in the internal milieu and, in the words of Broadbent (1981), are involved in "producing sensations of hunger, thirst, feeling of well-being, and others."

Since both the vestibular endorgans and length or tension receptors in joints, muscles and tendons are viewed traditionally as proprioceptive, balance (or equilibrium) has been viewed as a predominantly proprioceptive sense. However, one may argue cogently that balance control lies effectively at the interface between exteroceptive, proprioceptive, and interoceptive mechanisms. The contributions of visual fixation and optic flow to the visual dependence of balance (Redfern, Vanlley, & Heingstein, this issue) are exteroceptive. By the same token, visceral graviception (Balaban & Yates, in press; Muretsch, 1998) is clearly interoceptive. The convergence of at least proprioceptive (vestibular) and interoceptive (visceral) information in the parabrachial nucleus (Balaban, 1996; Balaban & Yates, in press), thus, is a potential substrate for parallel processes in balance control that cross the traditional boundaries of exteroception, proprioception, and interoception.

A more detailed model of the parabrachial nucleus network (Fig. 2) places the parabrachial nucleus within the functional context of neurologic substrates for fear and anxiety (Cheney & Deusch, 1996; Goudard & Charney, 1997). This schema is designed to illustrate possible substrates for the emotional consequences of afferent information about movement relative to a gravitational

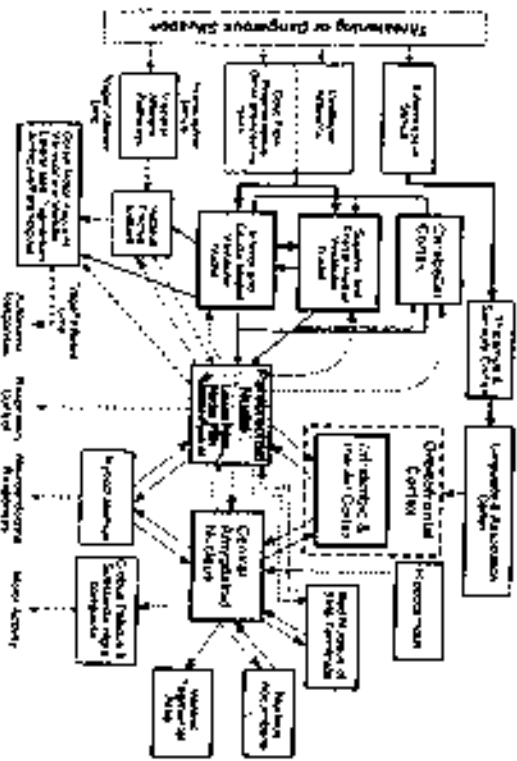

Fig. 2. Model of central circuitry associated with a neurologic linkage between balance disorders and anxiety disorders. See text for detailed description.

frame. From this diagram, one appreciates the strategic location of the parabrachial nucleus in both afferent sensory and efferent motor processing.

The parabrachial nucleus has been characterized as a parallel sensory relay for visceral information to the hypothalamus, amygdala, bed nucleus of the stria terminalis, and regions of orbitofrontal cortex (Kapp, Markgraf, Schwaber, & Balyk-Spatford, 1989; Lowry, 1990). This view emerged directly from anatomical connectives of the region, first, substrate of the parabrachial nucleus receive direct visceral sensory input (e.g., gustatory, cardiovascular, and respiratory-related afferents) from the nucleus tractus solitarius (Fulwider & Saper, 1984; Heber, Moga, & Saper, 1990) and direct exteroceptive input from the area postrema (Slapiro & Mivovis, 1985). Secondly, these parabrachial nucleus regions project to the amygdala, bed nucleus of the stria terminalis, hypothalamus, insula, and entorhinal cortex (Fernald, Allen, & Besson, 1993; Fulwider & Saper, 1984; Kapp et al., 1990; Moga et al., 1990). A role in visceral motor control was also suggested by the existence of (1) parabrachial connections, (2) parabrachial nucleus projections to respiratory control regions (e.g., phrenic motoneurons: Drobinske & Feldman, 1994; pharyngeal motoneurons: Hwang, Zeng, & Saki, 1999; and the ventral respiratory group: Morfin, Nunez-Alcalde, Ghyson, & Frenco, 1995), and (3) parabrachial nucleus projections to respiratory regions (such as nucleus tractus solitarius and the ventrolateral medulla) that affect sympathetic and parasympathetic outflow (Fulwider & Saper, 1984). Regions that chemically stimulate the parabrachial nucleus affect both respiratory pattern (Murolo, Bongiamini, Carli, & Panzetto, 1998) and cardiovascular function (Chamberlain & Saper, 1992; Hayward & Feller, 1998; Saito & Camuel, 1999) and are consistent with a premotor role of the parabrachial nucleus in respiratory and cardiovascular control pathways.

Other findings suggest an integrative role of the parabrachial nucleus in evaluation of the potential positive or negative emotional significance of multimodal stimuli. In addition to visceral sensory input, the parabrachial nucleus receives vestibular nucleus input (Balaban, 1996; Porter & Balaban, 1997) and spinal and trigeminal somatic sensory input (Reinold et al., 1995; Earl & Herlihy, 1995). In particular, the spinal and trigeminal projections to the external lateral parabrachial nucleus have been proposed as a nociceptive relay pathway to the central amygdaloid nucleus (Fassin, Burke, Cael, & Barham, 1997). Descending projections from the central amygdaloid nucleus, and nucleus of the stria terminalis, hypothalamus, insula, and entorhinal cortex to the parabrachial nucleus overlap extensively with different brainstem inputs and the locations of different efferent goals of parabrachial nucleus neurons (Moga et al., 1990; Yasui, Itoh, Takada, Kitano, & Mizuno, 1985). These dense inputs are likely to influence sensorimotor processing at this transition site.

The parabrachial nucleus has reciprocal connections with preencephalic structures that have been implicated in as participants in anxiety and panic disorders (Charney & Deusch, 1996; Goudard & Charney, 1997; Gantman et al., 1989; Pratt, 1992) and in changes in affect and conditioned emotional responses

(Deussen, 1998; Devinsky et al., 1994). The key features of this interconnected network comprising infralimbic and insular cortex, central amygdaloid nucleus, bed nucleus of the stria terminalis, and several hypothalamic regions (Antreas & Swanson, 1992; Carmichael & Price, 1995; Charney & Deusch, 1996; McDonald, 1994; Nalor & Winer, 1998; Shitsonaga, Takada, & Mizuno, 1992; Takajishi & Chiba, 1991) are summarized in Fig. 2.

Four major features of this network are worthy of note. First, the central amygdaloid nucleus and the bed nucleus of the stria terminalis are the two components of the 'extended central amygdala' (Adkins, DeOlinos, & Belfraim, 1995; Johnson, 1923). The extended central amygdala appears to be important for the expression of fear and anxiety (LeDoux, Iwata, Goshetti, & Klein, 1988). The central amygdaloid nucleus is an important mediator of autonomic and behavioral responses that are correlated with conditioned fear (LeDoux et al., 1988). Davis, Walker, and Lee (1997) have used studies of fear-conditioned startle reflexes to suggest further that the bed nucleus of the stria terminalis makes an important contribution to anxiety responses to longer term contextual cues. Both of these contributions seem germane to the spectrum of clinical phenomena comprised of space and motion sensitivity, space and motion discomfort, and space and motion phobia (Furman & Jacob, this issue).

A second important feature of the parabrachial nucleus network is the close involvement of the infralimbic cortex. The infralimbic cortex is included in a region termed the 'affective division' of the anterior cingulate cortex, which contributes to phenomena such as conditioned emotional learning, assessment of emotional content of stimuli, and generation of autonomic and endocrine responses (Devinsky et al., 1994).

A third significant feature is that the motor outputs of the parabrachial nucleus network can produce somatic, neuroendocrine, and visceral motor components of emotional responses. The multiple motor outputs of the parabrachial nucleus network are virtually identical to the output mechanisms described previously by Clancy and Deutsch (1996) for pathways subserving fear and anxiety. Briefly, the somatic and visceral motor output pathways of the parabrachial nucleus network are sufficient to explain the spectrum of fear and anxiety responses, including hormonal stress responses, changes in heart rate and blood pressure, pupillary dilation, perspiration, piloerection, hyperventilation, and anxiatic motor responses such as avoidance.

A fourth important feature of the parabrachial nucleus network is the ability to encompass a variety of triggers for anxiety and panic. Firstly, thalamocortical and thalamoamygdaloid connections of anxiety pathways provide exteroceptive visual, auditory, and somesthetic stimuli related to threatening or dangerous situations (Charney & Deusch, 1996). Secondly, both direct projections from nucleus tractus solitarius and indirect projections (from nucleus tractus solitarius and area postrema) via the parabrachial nucleus provide interoceptive visceral signals to anxiety pathways. In addition to sensing changes in cardiovascular and gastrointestinal function, these interoceptive signals are likely mediators of

anxiety and panic that is elicited by leptic, P_{CO_2} , and hyperventilation, when they may be interpreted as danger of suffocation (Klein, 1993). Thirdly, balance-related sensory signals can affect anxiety pathways in both thalamocortical and parabrachial nucleus pathways. Significantly, these pathways would also be sensitive to any nervous system dysfunction or drug action that results in asymmetric activity in the left and right vestibular nuclei and, hence, vestibulo. Finally, it is obvious that combinations of these exteroceptive, proprioceptive, and interoceptive stimulus modalities have the potential to interact in the pathways illustrated in Figs 1 and 2.

Studies of the role of the parabrachial nucleus for conditioned taste and odor aversions may provide insights into a more general role of the parabrachial nucleus network in mediating responses to aversive stimulus conditions, such as pain and spatial disorientation. Specifically, the examples of conditioned taste and odor aversions suggest that the combination of ascending sensory inputs and descending limbic inputs to the parabrachial nucleus may provide for a matching of external and internal stimuli and prior experience with an aversive context. Both conditioned taste aversion learning (Spector, Neagen, & Grant, 1993) and conditioned odor aversion learning (Grigson, Reilly, Scaleria, & Neagen, 1998) are impaired markedly after chemical lesions of the gustatory region of the parabrachial nucleus in rats. Significantly, lesions of the gustatory region of the parabrachial nucleus do not affect either discriminative taste performance (Spector et al., 1992), the ability to acquire a conditioned taste preference (Grigson, Reilly, Shimura, & Neagen, 1998), or the ability to acquire a conditioned aversion to capsaicin, the substance that produces the burning sensation from hot peppers (Grigson, Reilly, Shimura, et al., 1998). Since development of a conditioned taste aversion is unaffected by lesions of the gustatory region of nucleus tractus solitarius (Grigson, Shimura, & Neagen, 1997), the gustatory region of the parabrachial nucleus appears to be essential for the formation of the aversion. Since the physiologic responses of parabrachial nucleus cells to gustatory inputs are altered after formation of a conditioned taste aversion (Shimura, Tanaka, & Yamazaki, 1997), it is possible that the parabrachial nucleus functions both as a gateway and as a general contextual filter for relayng exteroceptive and interoceptive (e.g., cardiovascular, respiratory, chemoreceptive (e.g., suffocation alarm, Klein, 1993), and gastrointestinal sensory information to the amygdala, basal forebrain, and orbital frontal cortex.

3. Effects of emotions and anxiety on balance control

3.1. Phenomena

The schema in Fig. 2 proposes that a network involving the parabrachial nucleus can explain the ability of a variety of postural threats (e.g., balance, vestibular instability, cardiovascular signals, or signals indicating blood concen-

regions of within alcohol) can trigger either anxiety or a panic response. However, it is inadequate to explain a second aspect of the balance-anxiety link: the profound effects of vigilance, arousal, and anxiety on vestibulo-ocular reflex and balance performance.

Since the pioneering report by Hallpike, Harrison, and Slater (1951), other studies have reported that patients with panic disorder and agoraphobia show quantifiable differences between vestibular reflex performance and postural control responses (reviewed by Furnan & Jacob, this issue). However, there is also an extensive literature indicating that vestibular 'reflex' responses can be altered primarily by factors such as the performance of alerting tasks, drowsiness, 'unusual set', and administration of amphetamines (review Schumiger & Balaban, 1999). Since locus coeruleus appears to be involved both vigilance (Aston-Jones, Ching, & Alvarusky, 1991) and anxiety responses (Chamney & Deutsch, 1996; Gorman et al., 1989; Pratt, 1992), the dense noradrenergic innervation of the lateral vestibular nucleus by the cranial-vestibular pathways (Schumiger & Balaban, 1993, 1999) implied (1) that patients with anxiety and space and Motion Discomfort should show elevated postural sway during optic flow stimulation and (2) that the sway should be correlated with anxiety levels. The former prediction was tested by Jacob, Redfern, and Furnan (1995), who reported that elevated static postural sway persisted in space and motion phobic subjects after the conclusion of exposure to optic flow stimulation. In addition to confirming the earlier prediction, this persistence effect implies that anxiety per se may produce effects on vestibular reflexes and balance control that are akin to noradrenergic effects of alerting or increased vigilance. These persistence effects are potentially mediated by monoaminergic influences on the pathways illustrated in Fig. 2.

3.2. *Monoaminergic pathways: potential modulators of balance and anxiety*

In addition to a role in producing anxiety and panic disorders (Clancy & Jacob, 1996; Gorman et al., 1989; Jacob, Furnan, et al., 1996; Keane & Soubrie, 1991; Pratt, 1992), noradrenergic and serotonergic neurotransmission appear to have modulatory roles in vestibular pathways (Balaban & Vaiss, in press; Schumiger & Balaban, 1999). Noradrenergic and serotonergic axons originate from cell groups in the brainstem and terminate throughout the nucleus (Knaflitz & Grandjean, 1997; Moore & Bloom, 1979). These pathways appear to influence a wide variety of physiologic and behavioral processes, ranging from changes in arousal and sleep-wakefulness cycles to myelination of sensory processing and motor activity (Jacob, 1986; Jacobs & Azmitia, 1992; Jacobs & Fornal, 1993; Moore & Bloom, 1979). Activity of noradrenergic locus coeruleus neurons increases specifically in two situations (1) endogenous alertness and vigilant behavior elicited by exposure to novel or aversive sensory stimuli (Aston-Jones, Chang, et al., 1991; Aston-Jones, Frayn, & Bloom, 1984; Aston-Jones, Shipley, et al., 1991; Foote, Berridge,

Adams, & Pitroda, 1991) and (2) performance of tasks of exposure to situations that require the orienting of attention (Aston-Jones, Shipley, et al., 1991). Serotonergic activation, on the other hand, is believed to simultaneously facilitate motor output and inhibit sensory information processing, and to coordinate hormonal and neuroendocrine function in parallel with other programs (Jacobs & Fornal, 1993).

Dopaminergic neurotransmission may also affect neural resources in the vestibular nuclei (Crenace, Cotter-Enard, Requin, & Reyna, 1986; Warr, Serafin, Orshler, & Vidal, 1995) and both the extended central amygdala nucleus and infralimbic cortex (Fallon & Moore, 1979). The region of dopamine system innervates the forebrain comprises of the parabrachial nucleus network. Activation of the mesolimbic dopaminergic system has been implicated in stress responses (Inglis & McLaughlin, 1999), cognitive task performance (Maly, Szegedi, & Goldwater-Rakic, 1998), and the performance of goal-oriented behavior (Wise & Rompre, 1989). Hence, it is possible that changes in activity in the mesolimbic/dorsal dopamine system contribute to decrements in human performance of complex tasks (e.g., tracking tasks, tracing tasks, and navigation planning tasks) during exposure to repetitive motion in vehicles or simulators (review: Heringer, Kennedy, & McCarley, 1998).

Table 1 summarizes sources of monoaminergic innervation and receptor types (Bourguignon & Grandjean, 1997; Byrnes & Guyenet, 1987; Damyancic & Moolali, 1997; Inai, Stendler, & Kiki, 1986; Jacobs & Arnold, 1992; Kja et al., 1996; Larsen, Hays-Schmidt, Wang, & Mikelsos, 1986; Moore & Bloom, 1979; Morlock, Garlow, & Chiriacello, 1991; Muly et al., 1998; Passer & Palsson, 1985a, 1985b; Ruck et al., 1996; Scheinin et al., 1994; Schumiger & Balaban, 1999; Steinbusch, 1991; Veres, 1991; Vibert et al., 1995; Vincent, Khan, & Beres, 1993; Wilson & Molliver, 1991; Woulfe, Turnerfield, & Hrycihyn, 1993)

Table 1
Monoaminergic modulators in pathways linking balance and anxiety

Structure	5-HT sources (receptors)	DA sources (receptors)
Vestibular nuclei	5-HT _{1A} , 5-HT _{2A}	5-HT _{2A}
Parabrachial nucleus	5-HT _{1A} , 5-HT _{2A}	5-HT _{2A}
Extended central amygdala nucleus	5-HT _{1A} , 5-HT _{2A}	5-HT _{2A}
Hypothalamus including LHx	5-HT _{1A} , 5-HT _{2A}	5-HT _{2A}
PVN, VMN, MPO	5-HT _{1A} , 5-HT _{2A}	5-HT _{2A}

Abbreviations: LC, locus coeruleus; nucleus subpretectalis; 5-HT_{1A}, 5-HT_{2A}, 5-HT_{2C}, 5-HT_{2D}, 5-HT_{2E}, 5-HT_{2F}, 5-HT_{2G}, 5-HT_{2H}, 5-HT_{2I}, 5-HT_{2J}, 5-HT_{2K}, 5-HT_{2L}, expressed by neurons in key structures from pathways that link balance control and anxiety (Fig. 2).

3.2.1. Noradrenergic mechanisms

Central noradrenergic pathways originate from two major collections of brainstem neurons: (1) a locus coeruleus-nucleus subpretectalis region and (2) tegmental brainstem noradrenergic neurons that are found near the lateral reticular nucleus (A1), within nucleus tractus solitarius (A2), within the dorsal accessory olive (A3), and cells near the pool of the facial nerve region and trigeminal nuclei complex (A5 and A7) (Moore & Bloom, 1979; Moore & Card, 1984). These neuron groups have been viewed as separate subsystems that differ in their efferent connectivity (Fritschy & Cirranna, 1989, 1990; Moore & Bloom, 1979). Thus, effects of multiple noradrenergic pathways may have an impact on balance function and anxiety.

Recent studies of the afferent connections of locus coeruleus indicate that it receives prominent input from both the parabrachial nucleus network and central pathways that process vestibular information. Anatomical studies have demonstrated projections from the lateral parabrachial and Kölliker-Fuse nuclei (Lujić, Aston-Jones, Akonka, Chouvet, & Jouvet, 1995) and the central amygdaloid nucleus (Van Bockstaele, 1998) to noradrenergic locus coeruleus neurons. Anatomical (Fleiss, Shipley, Aston-Jones, & Williams, 1998) and electrophysiological (Fedo, Chuang, & Aston-Jones, 1998) evidence further indicates that there is a significant input to locus coeruleus from the medial prelimbic region of the prefrontal cortex, which includes infralimbic cortex. However, there are also several unidentified/prezonal sources of vestibular and/or balance-related information to locus coeruleus that produce spike discharges in response to vestibular stimulation (Barnes, Manzoni, Pontecorvo, Stampacchia, & d'Asciano, 1989; Pontecorvo, Manzoni, Barnes, Stampacchia, & d'Asciano, 1990). For example, one likely source of vestibular information is provided neurons in the ventral aspect of nucleus prepositus hypoglossus (Lujić et al., 1995), which are a source of dense afferent input to noradrenergic cells in locus coeruleus. In alert monkeys, this region of nucleus prepositus hypoglossus includes neurons that show vestibular responses and neurons that respond to eye and head velocity (McFarland & Fuchs, 1982). Sparse direct projections from the vestibular nucleus (Balaban, 1996; Cedarbaum & Aghajanian, 1978; Fung, Reddy, & Barnes, 1987) are a second potential source of balance information to the locus coeruleus. Finally, the afferent projections from the lateral parabrachial and Kölliker-Fuse nuclei are also possible sources of vestibular information (Balaban, 1996). These patterns of afferent input are consistent with an intimate contribution of noradrenergic locus coeruleus neurons to neural circuits at the balance-anxiety interface.

Recent studies have also indicated that the efferent organization of these pathways is more specific than believed previously. For example, locus coeruleus efferent projections show topographic features of organization (review: Schuërger

& Balaban, 1999). Firstly, anatomical studies have shown that locus coeruleus projections to sites such as the cerebral cortex, amygdala, and hypothalamus originate from partially distinct regions of the nucleus (Loughlin, Foote, & Bloom, 1986; Loughlin, Foote, & Cirranna, 1986; Mason & Fudge, 1979). Secondly, a single locus coeruleus neuron can send axon collaterals to multiple levels of the same sensory pathway (Simpson et al., 1997). Thirdly, the density of locus coeruleus innervation varies regionally among visual pathways (Moulton & Fawcett, 1986) and different subdivisions of the vestibular nuclei, particularly the origin of the lateral vestibulo-spinal tract (Schuërger & Balaban, 1993, 1999). Thus, it is possible that locus coeruleus neurons may have independent effects at the level of the vestibular motor pathways that contribute to postural responses and the components of the parabrachial nucleus network that are important for expressing fear, anxiety, and emotional responses.

The locus coeruleus appears to be the only source of noradrenergic innervation to the prefrontal cortex (Moore & Bloom, 1979) and the vestibular nuclei (with the exception of a few intrinsic noradrenergic cells) (Schuërger & Balaban, 1999). On the other hand, noradrenergic innervation of the parabrachial nucleus appears to originate from the tegmental groups (Bynum & Guyenet, 1987; Wouffe et al., 1990) and a few intrinsic neurons (Schuërger & Balaban, 1999). The extended central amygdaloid nucleus and hypothalamic regions, through receive noradrenergic input from both the locus coeruleus and the tegmental noradrenergic cell groups (Bynum & Guyenet, 1987; Moore & Bloom, 1979). Hence, differential effects of noradrenergic transmission on postural sway, emotion, and anxiety may be mediated by (at least partially) independent pathways on two levels: differential contributions of locus coeruleus and tegmental noradrenergic groups and differential topographic projections from locus coeruleus. The locus coeruleus and the cerebello-vestibular pathway is likely to mediate increases in postural sway and altered vestibular-evoked eye movements during anxiety and changes in alertness (review: Schuërger & Balaban, 1999). It is clearly of interest to determine whether specific enervation of locus coeruleus and tegmental noradrenergic activity contribute to the evolution of anxiety, panic, and emotional responses.

3.2.2. Serotonergic mechanisms

Central serotonergic pathways originate from the mesencephalic and rhombencephalic raphe nuclei and adjacent brainstem vesicular formation (Haungarten & Grodzanovic, 1997; Jacobs & Azmitia, 1992). Since these serotonergic cell groups, however, differ in both their coexpression of putative peptide neurotransmitters (e.g., galanin, substance P, calcitonin gene-related peptide, and enkephalins) and efferent targets (Haungarten & Grodzanovic, 1997; Jacobs & Azmitia, 1992), it is important to remember that the effects of activation of the raphe nuclei may be regionally selective. The potential intricacy of serotonergic transmission is magnified by the presence of multiple receptor types, which may produce complex responses to serotonin in the same neuron (e.g., cerebellum

Thickve cells; Dawson, Strahlendorf, & Strahlendorf, 1990; Lu, Wang, Strahlendorf, & Strahlendorf, 1993; Strahlendorf, Lee, & Strahlendorf, 1994; Wang, Strahlendorf, & Strahlendorf, 1992). However, Jacobs and Fornal (1993) have presented the interesting and compelling hypothesis that there are two net behavioral effects of serotonergic transmission that are germane to the circuitry linking habitic control and anxiety: first, they argue that serotonergic activation simultaneously facilitate motor output and inhibit sensory information processing. Since expression of fear and anxiety is regarded as a form of motor output, this hypothesis would predict serotonergic enhancement of both vestibular reflexes and the parabrachial nucleus network. Secondly, Jacobs and Fornal (1993) suggested a parallel action consistent with activation of the parabrachial network: Serotonergic activation coordinates humoral and neuroendocrine function in parallel with motor programs.

The raphe nuclei receive input from a wide variety of sources (review: Jacobs & Azmitia, 1992), including noradrenergic input from locus coeruleus and nucleus subpretecticus, adrenergic input from the dorsal medulla (nucleus tractus solitarius or petillojugularis tract), dopaminergic input from the ventral tegmental area and substantia nigra, and peptidergic inputs from the central gray. Several other sources are particularly germane to the schema in Fig. 2. The vestibular nuclei directly influence the raphe nuclei, via direct connections from the vestibular nuclei to the dorsal raphe nucleus (Kalten, Kalsun, & Wihlwald, 1985; Kawasaka & Sato, 1981), nucleus raphe magnus (Balaban, 1996; Carlsson, Leichnetz, Young, & Mayer, 1983) and nucleus raphe pontis (Turner, Whorff, & Magnus, 1983). Sensory and sensorimotor signals related to visceral function also influence the raphe nuclei via direct connections from nucleus tractus solitarius, parabrachial nuclei, and ventrolateral medulla (review: Ramangasari & Grossa, 1997). The raphe nuclei also receive descending inputs from the lateral hypothalamus, hind nucleus of the stria terminalis, and orbital frontal (prefrontal) cortex (Jacobs & Azmitia, 1992; Wysz & Stripoldwichai, 1984). Hence, discharges of serotonergic raphe neurons have the potential to grade information regarding both a (vestibular or visceral) stimulus and contextual information related to the status of anxiety and emotional responses.

Vestibular nucleus neurons respond to exogenous serotonin (Johnston, Murray, McQueen, & Dulla, 1993; Leticia, La Voita, Møllgaard, Cirranna, & Santanelli, 1993; Leticia, La Voita, Møllgaard, & Santanelli, 1993) and stimulation of the dorsal raphe nucleus (Kashimoto, Sasa, & Takano, 1991; Leticia et al., 1993; Lu, Voths, Leticia, Cirranna, and Santanelli (1993)) reported recently that local application of serotonin into the lateral and inferior vestibular nucleus increased electromyographic responses of limb muscles via the lateral vestibulospinal tract and that 5-HT_{2A} antagonism partially blocked the effect. Since microanalysis studies suggest that serotonin release parallels the degree of behavioral or motor arousal at a variety of central sites (Kucner, Fornal, & Jacobs, 1997), actions of serotonin in the vestibular nuclei would be expected to increase the sensitivity of the lateral vestibulospinal tract with increasing arousal. Thus, serotonergic and

noradrenergic activity may act synergistically during anxiety to increase postural sway through actions in the vestibular nuclei.

The ascending raphe projections to the extended central amygdaloid nucleus, hypothalamus, and infolimbic cortex are a potential substrate for at least two effects: (1) coordination of noradrenergic and hormonal responses with autonomic motor activity and (2) alterations in current anxiety state. These effects may be regionally specific because the raphe nuclei project in a roughly topographic manner to prefrontal cortex, the amygdala (including the extended central amygdaloid nucleus) and the hypothalamus (Inai et al., 1986; Jansen et al., 1996; Wilson & Krolliver, 1991). Furthermore, it is not clear that any single receptor subtype may produce similar behavioral effects across these structures. Thus, the sites underlying the partial efficacy of serotonin raphe-like inhibitors in panic disorder are unclear.

Serotonergic mechanisms have also been implicated in the pathogenesis of migraine, a disorder that is associated in a significant proportion of patients with vertigo (Baloh, 1997; Harker, 1996; Kayan & Iltis, 1984; Swenson, Carroll, Davies, & Jaxson, 1997), a history of motion sickness (Raitio, 1997), and space and motion disorientation (Baloh, 1997; Cass et al., 1997). Experimental evidence suggests that serotonin mediates the generation of migraine pain via 5-HT_{1D} and receptor mechanisms at peripheral trigeminovascular terminals (Lamotte, Carter, & Moskowitz, 1996; Moskowitz, 1993) and at central trigeminal nuclear sites (Goadsby & Haxton, 1998; May & Goadsby, 1999). Although the role of serotonin in migraine-associated vertigo is unknown, it has been suggested that analogous mechanisms occur in the inner ear and central neural system (Clair & Baloh, 1992). Despite the uncertainty regarding the underlying pathophysiology of migraine-associated vertigo, a vertiginous aura, vertigo, phonophobia, and photophobia are clear candidates for eliciting stimuli for avoidance or retreating stimuli for conditioned avoidance. Two likely explanations for the comorbidity of migraine and panic disorder (Stewart, Breznan, & Keck, 1994) can be envisioned from the schema in Fig. 2. First, as described in an earlier section, signals reflecting pain and vestibular activation reach the parabrachial nucleus network via direct projections from nociceptive trigeminal nuclear pathways (Lisman et al., 1997) and the vestibular nuclei to the parabrachial nucleus. Secondly, trigamine-associated changes in regional blood flow or neural activation in the anterior cingulate cortex (May & Goadsby, 1999) may also activate in the extended amygdaloid nucleus and prefrontal cortex.

3.2.2 Dopaminergic mechanisms

Empirical evidence indicates that several drugs with significant histamine-H₁ and dopaminic (D₂) antagonism at (propranolol, prochlorperazine, chlorpromazine, haloperidol, and domperidon) are efficacious for treatment of vestibular dysfunction (Wackym & Balaban, 1998). Clozapine is another example of a drug that provides symptomatic relief of vertigo (Jacobi, personal communication; Johnston, 1998) and also affects central dopaminergic function (e.g., Tom &

Niles, 1995). Dopaminergic transmission (of unknown origin) in the vestibula nuclei (Crumm et al., 1996; Villet et al., 1995) and mesolimbic dopaminergic projections to the extended central amygdaloid nucleus and infralimbic cortex (Kilian & Moore, 1978) are potential substrates for D₂-receptor-mediated dopaminergic transmission to influence vestibular function and anxiety. Further research is needed to clarify the potential contributions of dopaminergic mechanisms to balance control.

4. Pharmacotherapy for patients at the balance-anxiety interface

Empirical observations from pharmacotherapy are also consistent with the concept that balance disorders and anxiety disorders may share common neurochemical bases. Recent clinical practice indicates that clonazepam, beta blockers, and antidepressants often provide symptomatic relief for patients with either a balance disorder with which they cope poorly or migraine-related vertigo (Jacob, personal communication, Johnson, 1998). The use of both selective serotonin reuptake inhibitors (SSRIs) and non-SSRI tricyclic antidepressants have been described in the neuro-otologic literature (e.g., Johnson, 1998). Clonazepam is administered in a dose similar to that for panic disorders (Jacob, personal communication, Johnson, 1998) and it provides rapid symptomatic resolution. Antidepressants, on the other hand, are administered in doses ranging from a small fraction (e.g. one-sixth) to the normal dose range for panic disorders; unlike clonazepam, they do not offer immediate symptomatic relief. The sites and mechanisms of action that account for the efficacy of these medications in vertigo are unknown. However, the presence of benzodiazepine binding (Nehring, Koch, & Buzsaki, 1989) and serotonin receptor mechanisms in the cerebellar cortex, vestibular nuclei, and parabrachial nucleus network raises the likelihood that these drugs may act simultaneously in both vestibular pathways and more rostral circuits related to anxiety and panic responses.

The SSRI discontinuation syndrome also provides intriguing evidence for a neuro-behavioral linkage between anxiety and balance mechanisms. Specifically, the acute onset of dizziness, vertigo, and incoordination, exacerbated by head and eye movements, is a hallmark of the SSRI discontinuation syndrome (Black, Wesner, & Gabel, 1993; Coupland, Bell, & Perokar, 1996; Haddad, 1997; Maravitz & Greden, 1998; Scharfberg et al., 1997; Zajacka, Tracy, & Mitchell, 1997). The prevalence of these balance symptoms varies among SSRIs, they appear to be encountered most frequently with fluoxetine and paroxetine, and more rarely with sertraline and fluoxetine (Coupland et al., 1996; Haddad, 1997; Mainer & Greden, 1998; Scharfberg et al., 1997). These symptoms have a sudden onset, usually during the first week of discontinuation of the SSRI, and may persist for weeks. Estimates in general patient populations indicate a prevalence less than 20% (Coupland et al., 1996). However, it is perhaps noteworthy that 11/14 (76%) panic disorder patients developed

balance control symptoms within 5 days of discontinuation of fluoxetine (Black et al., 1997). The exacerbation of these balance symptoms by head and eye movements is suggestive of effects at the level of sensory receptors, the brainstem, or cerebellum.

5. Integrative summary

Fig. 3 presents an overview of the relationship of anxiety and panic in association with balance control. Balance-related and visceral information from vestibular, visual, proprioceptive, and interoceptive afferent pathways are processed initially in the brainstem. Information processing at the brainstem level, though, is influenced by (1) cerebellar minimization, which is likely to contribute to coordination, prediction, habituation, and classical conditioning of responses (Balaban, 1996; Ito, 1984) and (2) descending commands and feedback from the telencephalic and hypothalamic components of the parabrachial nucleus network. This brainstem-cerebellar network then participates in generation of both somatic motor (e.g., postural adjustments, eye movements, and changes in respiratory rate) and visceral motor responses (changes in blood pressure, heart rate, uterine and gastrointestinal functional, and peripheral information about the gravitational frame to the parabrachial network and monoaminergic pathways).

The parabrachial nucleus network is hypothesized to maintain a context-dependent representation of sensory information, somatic motor activity, and visceral motor activity. This integrated representation reflects current and anticipated patterns of postural sway, eye movements, autonomic nervous system activation, and incidents exteroceptive, proprioceptive, and interoceptive sensory signals. The exteroceptive (visual and tactile) and proprioceptive (vesibular and joint and muscle receptor) sensorimotor information are relayed directly to perception of postural stability in extrapersonal space. They may engage in control from benign (within normal limits) to a danger of loss of balance, falling, and injury. The interoceptive signals, though, are more routinely associated with a context of movement and postural stability. Further, visceral sensations such as epigastric queasiness or discomfort and unexplained heart palpitations are more closely associated with aversive visceral (e.g., gastrointestinal distress) or emotional (e.g., fear) contexts (Muller, Koch, Stern, & Thayer, 1999; Mells, Thayer, Stern, Friedman, & Drake, 1998). Hence, it has been suggested that these interoceptive responses may be regarded as *reflexes of visceral discomfort* from a somatic stimulus during either vestibular dysfunction or development of motion sickness. The aversive aspects of these sensorimotor and contextual signals produce the symptom dimension (Furman & Jacob, this issue) termed Space and Motion Discomfort.

The central concept of this schema is that the parabrachial nucleus maintains a representation of an internal sense of well-being (or lack thereof) and, con-

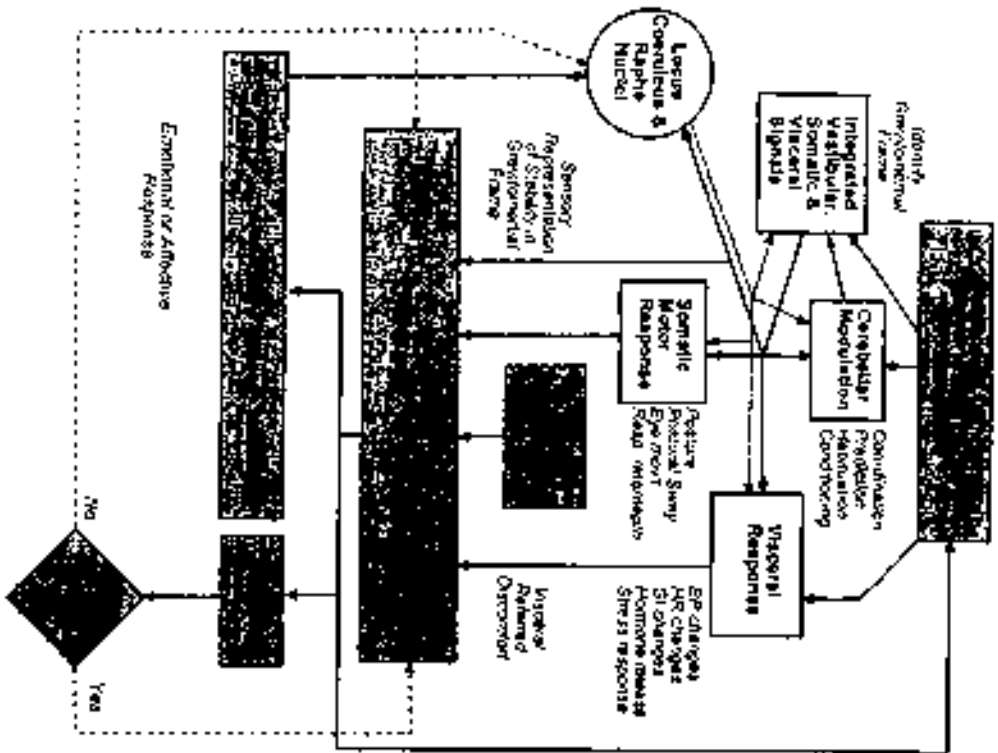

Fig. 3. Heuristic description of operations of the neurounger linkage model. Emotional components within the parameters of a client scenario (shaded region in Fig. 1) are also thought in these relations. See text for detailed discussion.

eventually, participants in the generation of emotional (or affective) and behavioral responses. The possible emotional responses range from ease (euphoria) to a panic attack. The possibility of escape or avoidance from either an anticipated or unexpected threat can either mitigate (if the situation is avoidable)

or exacerbate (if the situation is unavoidable) an evolving sense of distress and an anxiety response. Behavioral (motor) responses are mediated directly by descending commands to the brainstem circuitry and indirectly via locus coeruleus and the raphe nuclei. Since the noradrenergic inputs appear to increase the sensitivity of vestibular reflex pathways to vestibular input, activation of these pathways with increasing vigilance, and anxiety (or extreme postural sway), exacerbate an internal sense of distress and produce Space and Motion Discomfort.

Furman and Jacob (this issue) have defined Space and Motion Phobia as a specific phobia of situations that elicit space and motion discomfort. The development of the phobia seems analogous to conditioned fear, which requires an intact central amygdala/nucleus (see discussion above). Hence, one may envision a continuum of responses to space and motion stimuli, mediated by modifications of neural processing in the parabrachial nucleus network and ranging from stimulus to Space and Motion Discomfort to Space and Motion Phobia.

A clinical taxonomy of dizziness and anxiety in the otoneurological setting

Joseph M. Furman*, Rolf G. Jacob

University of Pittsburgh School of Medicine, Pittsburgh, PA, USA

Abstract

Dizziness can be associated with otologic, neurologic, medical, and psychiatric conditions. This paper focuses on the interface between otologic and psychiatric conditions. Because dizziness often is situation specific, concepts of space and motion sensitivity (SMS), space and motion discomfort (SMD), and space and motion phobia (SMP) are needed to understand the interface. We present a framework involving several categories of interactions between balance and psychiatric disorders. The first category is that of dizziness caused by psychiatric disorder (psychiatric dizziness), including hyperventilation-induced dizziness during panic attacks. The second category involves chance cooccurrence of a psychiatric disorder and a balance disorder in the same patient. The third category involves problematic coping with balance symptoms (psychiatric overlay). The fourth category provides psychological explanations for the relationship between anxiety and balance disorders, including somatopsychic and psychosomatic relationships. The final category, neurological linkage, focuses on the overlap in the neurological circuitry involved in balance disorders and anxiety disorders. © 2001 Elsevier Science Inc. All rights reserved.

Keywords: Vestibular disorders; Anxiety disorders; Panic; Agoraphobia; Space and motion discomfort; Visual cliff; Migraine-related dizziness; Fear of heights

1. Introduction

In this paper, we will discuss the various ways in which dizziness, balance disorders, and anxiety or other psychiatric conditions may interact clinically. Our

discussion of this interaction includes a description of the symptomatology of dizziness and the concept of space and motion sensitivity (SMS) and space and motion discomfort (SMD) as they occur in anxiety disorders and vestibular disorders. After laying this foundation, the interface between vestibular and psychiatric disorders in general will be explicated, from the perspective of an otoneurological clinician in a dizziness clinic.

Dizziness as an experience is internal or private in nature. As with other private sensations (e.g., pain), the verbal labeling of the experience is not subject to direct social validation. Therefore, different verbal descriptors are used by different individuals, and conversely, the same verbal descriptor may mean different sensations for different individuals. Synonyms for dizziness often are defined by an analogy to physical events or actions, such as voluntarily hyperventilating, voluntarily spinning around, or taking an amusement park ride. Terms such as floating, spinning, swimming, walking on clouds, giddiness, feeling unreal, disoriented, or lightheaded all have connotations to external actions or events. Note that many of these terms do not connote a sense of "spinning."

2. Dizziness in panic disorder

In medical practice, the patient's description of their dizziness has been considered a clue to the etiology of their problem. For example, spinning of the environment has been considered suggestive of a balance disorder, whereas spinning in the head has been considered suggestive of a psychiatric disorder.

Table 1

Prevalence of dizziness-related symptoms during and between panic attacks in patients with panic disorder with or without agoraphobia

	During panic ("often" or more)		Between panic ("sometimes" or more)	
	Sample 1 ^a (%)	Sample 2 ^b (%)	Sample 1 ^a (%)	Sample 2 ^b (%)
Lightheadedness	70	69	64	60
Dizziness	51	54	49	46
Feeling like drifting	63	51	31	29
Disoriented and confused	47	49	38	41
Wobbly legs	41	43	27	37
Feeling like falling	27	34	23	29
Tendency to fall	25	33	24	31
Spinning in head	39	44	31	43
Room spinning	22	29	21	20
Veering to the left or right	10	14	14	13

^a Sample 1, N=29

^b Sample 2, N=35

Unfortunately, such inferences are not accurate. For example, patients with panic disorder report the symptom of environment spinning both during and between panic episodes. We examined our data from two cohorts of patients with panic disorder who completed our "Symptom Questionnaire" (Jacob, Libsonfeld, Furman, Durrant, & Turner, 1989). Table 1 shows the findings for dizziness and related items. We found, first, that dizziness described as "lightheadedness" is very common, occurring "often" or more in the panic attacks of 70% of the patients. This sensation is commonly attributed to be a consequence of hyperventilation. However, 23–29% of the patients endorsed the item of "room spinning" during their panic attacks. Similarly, 20–24% reported "room spinning" as occurring "sometimes" or more between panic attacks.

3. Dizziness in balance disorders

Fig. 1 provides a framework for classifying patients with a chief complaint of dizziness. Dizziness is the primary complaint in 2.6% of primary care visits (Sloane, 1989). At the center (area A), we find a core of relatively well-defined clinical syndromes. We will discuss some of these syndromes below. Outside of the square of syndromal dizziness fall the many patients who have a balance system disorder that cannot be assigned a specific diagnosis (area B). Rather, such patients have examination or laboratory abnormalities that suggest a balance system disorder, but the etiology is uncertain. Such patients may receive a provisional diagnosis such as vestibulopathy of unknown etiology or dysequilibrium of the elderly. Some dizzy patients have symptoms that are highly suggestive of a balance disorder but have no objective signs to substantiate even a provisional neurologic diagnosis (area C). Finally, dizziness may occur in individuals with no balance disorder (area D). For example, dizziness is a common sign of orthostatic hypotension. Finally, not shown in the figure are individuals with asymptomatic pathological lesions in the vestibular system. For example, patients with slow-growing acoustic neuromas (vestibular schwannomas) may have no dizziness, even though such patients may have an unusual sensitivity to visual spatial cues (Bles & Roos, 1991).

Neurologic syndromal disorders are typically classified depending on whether they primarily involve the peripheral or central vestibular system. Estimates of their prevalence appear in Table 2. Peripheral vestibular dysfunction implies that the problem (lesion) is located in the inner ear or the eighth cranial nerve. The most common *peripheral vestibular syndromes* include benign paroxysmal positional vertigo (BPPV), Ménière's disease, i.e., endolymphatic hydrops, and vestibular neuritis. Many persons have probably suffered from a mild peripheral vestibular ailment, but their symptoms are subclinical because of central nervous system compensatory processes. Bilateral vestibular loss is not very common but should be mentioned as an extreme example of how some

Fig. 1. Framework for a taxonomy of dizziness. This Venn-type diagram is meant to illustrate the overlap between neurologic and psychiatric etiologies for dizziness. Note that dizzy patients can manifest a neurologic (balance) disorder, a psychiatric disorder, or both. Moreover, because of the difficulty in establishing a neurologic diagnosis definitively, there are subgroups of patients with sub-clinical balance disorders, non-syndromal balance disorders, and those with a well-defined neurologic syndrome. A contemporaneous psychiatric disorder can be seen with all groups.

patients with reduced or absent peripheral vestibular function, must rely upon non-vestibular information for their balance. Finally, as noted above, patients with acoustic neuromas do not often present with dizziness, but the presence of an intracranial neoplasm is obviously a major concern in the differential diagnosis of dizziness.

BPPV is characterized by brief, i.e., 10- to 30-s episodes of vertigo induced by particular changes in head position such as rolling over in bed or pitching the head backward to look up. BPPV is caused by free-floating debris in the endolymph of the semicircular canals, typically in the posterior semicircular canal (Baloh, 1996). Although most patients with BPPV describe their dizziness as a sense of spinning or as vertigo, they may complain of lightheadedness or a floating sensation, especially when recumbent. Many patients with BPPV report a sense of fear during their acute attacks.

Menière's disease, i.e., endolymphatic hydrops, is a disorder characterized by episodes of severe vertigo lasting for minutes to hours typically accompanied by unilateral hearing loss, tinnitus, and ear fullness. Patients with Menière's disease

Table 2
Prevalence of neuro-otologic syndromes

	EPVV	Ménière's disease	Migraine-associated dizziness	Unilateral vestibular loss	VBI	Head trauma
Dominic et al. (1985)	17.1%	9.8%	27.3*	5.2%	3.2%	5.5%
Population estimates (Kujawa et al., 1991)	10.7/10 ³	200/10 ⁴	6.3%	-	-	-
		(Kujawa & Neeb, 1984; Fucci, Mezin, & Kurland, 1984)	(Kagan & Hood, 1984; Stewart et al., 1994b)			

EPVV: benign paroxysmal positional vertigo, VBI -- vertebro-basilar insufficiency
* From Saunders, Carroll, Davies, and Luvon, 1997

also may have numerous minor episodes that are brief and occur between their major episodes. The cause of endolymphatic hydrops is unknown but is thought to be related to abnormal fluid balance in the inner ear. Menière's disease can be a sequela of viral infections of the inner ear and of trauma. During acute Menière's attacks, patients typically describe vertigo or "spinning." However, this spinning may refer to either themselves or to the surroundings. During minor Menière's attacks, patients may describe their dizziness using any of the terms discussed in the Introduction. As with BPPV, patients often become frightened during Menière's attacks. The symptoms of Menière's disease are particularly disturbing because they come without warning and may occur during virtually any activity, even sitting still or during sleep.

Vestibular neuritis, also known as labyrinthitis, is characterized by a severe vestibular syndrome associated with vertigo, nausea, and vomiting. Such patients typically have a monophasic course with acute symptoms for 1-2 days followed by gradual recovery of balance function. Vestibular neuritis results in a loss of peripheral vestibular activity on the affected side that may be lifelong. Following the acute peripheral vestibular insult, patients recover through a process known as "vestibular compensation." Compensation is a process that is characterized by alterations in central nervous system processing of balance information so that the individual can use the remaining sensory information from the normal labyrinth and information from the visual and somatosensory systems to maintain postural stability and stable vision. Compensation typically occurs over a matter of days to weeks. Once compensated, many patients develop an increased reliance upon either visual or somatosensory information and may be entirely asymptomatic. Usually, however, patients report dizziness with rapid head movements. Patients with vestibular neuritis often complain of spinning or vertigo during the first few days of their illness and later describe their dizziness using any of the terms noted in the Introduction.

Bilateral vestibular loss can be a result of ototoxic drug exposure, e.g., treatment with aminoglycoside antibiotics or chemotherapy such as cisplatinum, a sequela of autoimmune disease of the inner ear, or idiopathic. Regardless of the etiology, patients with bilateral vestibular loss typically manifest oscillopsia and ataxia. Oscillopsia is a jumbling of the visual surround, which in patients with bilateral vestibular loss is often experienced during head movement. Patients with bilateral vestibular loss are particularly challenged in dark or dimly lighted environments because of their reliance on vision.

Common central vestibular disorders include migraine-associated dizziness, the sequelae of head trauma, and vertebralbasilar insufficiency (VBI). Migraine-associated dizziness is an underrecognized balance disorder that is actually quite common (Johnson, 1998) (see Table 2). Recent data suggest that migraine-associated dizziness is the most prevalent form of dizziness in the population, with a 1 year prevalence of about 6.5% (Kayan & Hood, 1984; Stewart, Schochler, & Rasmussen, 1994). Many patients with migraine headache suffer dizziness with some or all of their headaches. Patients may complain of dizziness

before, during, or after a migraine headache. Other patients with known migraine headache may suffer from migraine-associated dizziness in isolation, i.e., dizziness without headache. Although, vertigo, i.e., spinning, is common, many migraine patients experience a sense of spatial disorientation and complaints may include any of the terms mentioned in the Introduction. A recent study by Cass et al. (1997) has indicated the large variability in the duration of symptoms in patients with migraine-associated dizziness.

Head trauma can produce dizziness, especially as a feature of so-called "postconcussion syndrome." This dizziness is often nonspecific and its origin is uncertain. Possibly, a brainstem rather than a cerebral concussion is responsible for dizziness in some patients. A complicating factor in the evaluation of a patient who has suffered from head trauma is that the inner ear or the neck may be damaged in addition to the brain.

A simple demonstration highlights the importance of afferent information from the neck. First, assume that the head is turned to the left. If the body leans forward, the head will move from left to right (in head coordinates). Now, assume that the head is turned to the right. If the body leans forward, the head will move from right to left. Thus, the central nervous system must interpret the signals from the labyrinth in light of the orientation of the head on the torso. Any traumatic injury that impairs the ability of the central nervous system to locate accurately the head on the torso, e.g. a neck injury, can produce dizziness and dysequilibrium.

Patients who have suffered head trauma often provide a very nonspecific and vague description of their dizziness. Vertigo and spinning are rare. More commonly, they describe floating, giddiness, and other nonvertigo, nonspinning terms.

VBI refers to a transient ischemic attack affecting the posterior circulation, which supplies the labyrinth, the brainstem, the cerebellum, and the occipital lobes. With a prolonged compromise in the vertebrobasilar circulation, an infarction of the labyrinth, brainstem, cerebellum, or occipital lobes or some combination may occur. Establishing the diagnosis of VBI without infarction is more problematic since symptoms and signs are transient. Dizziness alone is infrequently the presenting sign of VBI (Fisher, 1967; Grad & Batohi, 1989). The patient's description of their dizziness with VBI can include any of the terms mentioned in the Introduction.

4. Vestibular dysfunction, central compensation, and SMS

An overlooked aspect of vestibular symptomatology is that it can be situation specific. The situational aspects of vestibular symptoms are explained by the fact that the balance system receives input from three sensory systems, the visual system, the somatosensory system, and, of course, the vestibular system. Even individuals with normal balance systems utilize the nonvestibular

channels. For example, body sway in the standing position is higher when a person's eyes are closed as opposed to open. Similarly, even normal individuals report symptoms of height vertigo (Brandt, Arnold, Hies, & Kapteyn, 1980) and show increased body sway when exposed to heights when no nearby objects are present in the visual surround (Bles, Kapteyn, Brandt, & Arnold, 1980). An important consequence of the presence of three separate balance system inputs is the possibility of "mismatch," i.e., inconsistencies among the visual, vestibular, and somatosensory signals important for balance. A mismatch among the senses can occur transiently in normal individuals in certain situations, e.g., looking at the speedometer while driving around a curve, where vision tells us that we are not moving, but the vestibular and somatosensory channels tell us that we are moving. Unexpected mismatch tends to lead to conscious vestibular sensations. Many amusement park experiences derive their effectiveness by "designed" mismatch. Prolonged exposure to situations involving mismatch is known to elicit motion sickness (Reason & Brandt, 1975).

The balance system is quite plastic in the sense that the central nervous system can alter its patterns of sensory integration. The drive to such an alteration is usually a mismatch among the senses. Vestibular lesions may change the input in the vestibular channels in ways not matched by the other channels. Therefore, long-term alterations in sensory-motor processing can occur in patients with a vestibular lesion. For example, individuals with vestibular dysfunction may develop a sensory integration strategy in which visual information, somatosensory information, or both are used to replace the reduced or misleading information in the vestibular channel. These patients show an unusual sensitivity to, or need for, visual and/or somatosensory information to maintain balance. Furthermore, some patients with vestibular disorders become overly sensitive to intense vestibular stimulation, for example, during and immediately following a rapid head turn. In either case, situationally specific balance-related symptoms, SMD may arise. SMD is a key concept for understanding the relationship between balance disorders and anxiety disorders. Some clinically relevant consequences of SMS and SMD are shown in Fig. 2.

One way in which SMS manifests is by increased body sway or poor balance in environments with inadequate or misleading balance information. Thus, patients with bilateral vestibular dysfunction have particularly poor balance performance when both the visual and somatosensory information is degraded. Similarly, during recovery from unilateral labyrinthectomy, patients show impaired performance in balance test conditions in which both visual and proprioceptive input is minimized (Fetter, Dieter, & Dichgans, 1991). It has been found that, when exposed to simulated moving visual environments (optic flow stimuli), patients with balance disorders had increased body sway (Caselbrant, Redfern, Furman, Fall, & Mandel, 1998; Redfern & Furman, 1994; Redfern, Yardley, & Bronstein, this miniseries). Similarly, patients with acoustic

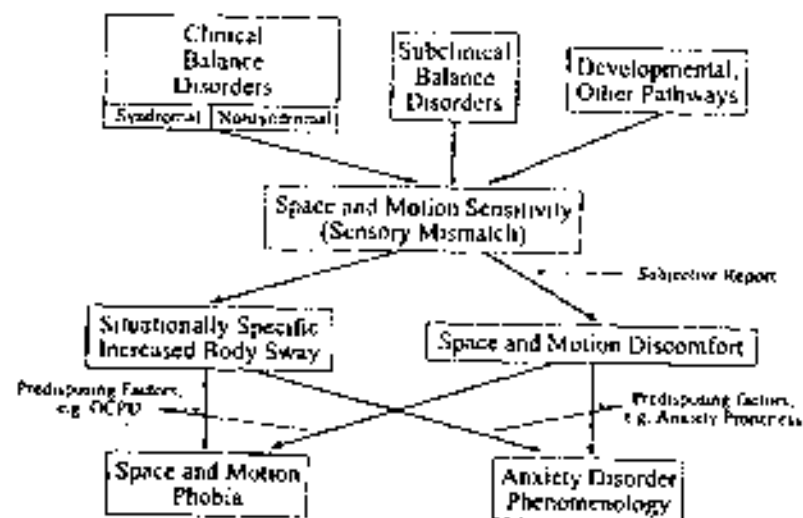

Fig. 2. Flow diagram for space and motion sensitivity. SMS represents a common manifestation of abnormal sensory information for balance or abnormal processing of balance information. SMS can manifest SMD in some patients and/or situationally specific increased body sway. These can evolve into anxiety phenomenology and SMP in certain individuals.

neuromas without any complaints of dizziness have impaired performance in a rotating room (Bles & Roux, 1991). We have found that optic flow sensitivity increases in children with otitis media, a condition that may impair vestibular function. (Casselbram et al., 1998).

There may be other pathways leading to SMS besides vestibular dysfunction (see Fig. 2), including maturation and learning. During postnatal development, postural sensitivity to optic flow in the peripheral visual field develops at about 8 months of age, after infants have had experience with crawling or ambulating (Berthenthal & Bai, 1989; Higgins, Campos, & Kermonat, 1996). This sensitivity emerges despite the fact that the vestibular system in infants is characterized by increased gain compared to adults (Ornitz, Kaplan, & Westlake, 1985). The onset of optic flow sensitivity appears to coincide with the development of fear of heights as well as wariness of the visual cliff, a laboratory analogue to fear of heights (Campos, Berthenthal, & Kermonat, 1992). Thus, experience in crawling seems to be a necessary condition both for both peripheral optic flow sensitivity and fear responses to the visual cliff. However, infants who had learned to crawl very early, before 6.5 months of age, did not later develop fear of the visual cliff (Rader, Bausano, & Richards, 1980; Richards & Rader, 1981), a finding attributed to early crawlers learning to crawl during a period of tactile rather than visual dependence (Rader et al., 1980). With increasing age beyond infancy, sensitivity to optic flow diminishes (Butterworth & Cicchetti, 1978; Butterworth

& Hicks, 1997; Casselbrant et al., 1998; Stoffregen, Schmuckler, & Gibson, 1987). This age-dependent pattern of optic flow sensitivity appears to mirror that of the age-dependent prevalence of fear of heights and may explain the frequent childhood onset of height phobia, compared to other environmental fears (Craske et al., 1996). It is possible that the early peak of onset of height phobia represents the persistence of the normal wariness of heights in infants.

Another manifestation of SMS is symptoms report. Patients with balance disorders may report that they feel uncomfortable in certain spatial environments such as shopping malls and grocery stores, and with certain movements such as bending over or shaking one's head vigorously. Thus, SMS may give rise to SMD (see Fig. 2). SMD is defined as symptoms elicited by environmental stimulus constellations "characterized by inadequate visual or kinesthetic information for normal spatial orientation" (Jacob et al., 1993). As a symptom dimension, SMD can be measured by the "Situational Characteristics Questionnaire" (Jacob et al., 1989, 1993). A related concept is *visual vertigo* (Bronstein, 1995). Visual vertigo is triggered by complex visual environments such as shopping malls, or by busy floor or wallpaper patterns, particularly those involving patterns that provide competing stimuli for visual fixation.

In a study of patients with dizziness, we found that patients with balance disorders, unlike those evaluated for mild hearing loss, reported discomfort looking up at tall buildings, closing eyes in the shower, or leaning far back in a chair. Similarly, they reported increased discomfort on winding roads compared to straight ones, glass elevators compared to standard ones, and crowded compared to empty supermarkets or elevators (Jacob et al., 1993). They also reported fear of heights and fear of boats (Clark, Hirsch, Smith, Furman, & Jacob, 1994).

The phenomenon of SMS and SMD may explain why some patients with balance disorders develop fears in the agoraphobic spectrum, including "street neurosis," the "supermarket syndrome," the "motorist vestibular disorientation syndrome," and "space phobia" (Jacob, Furman, & Balaban, 1996). Similar situation-specific symptoms are not observed in other neuro-otologic conditions, such as hearing loss or tinnitus. In fact, tinnitus shows a relationship with depression rather than anxiety (Simpson, Nodzenski, Barber, & Thomas, 1988). Patients with agoraphobia identified in an anxiety disorders clinic setting report SMD to a degree similar to that found in balance patients (Jacob et al., 1993). The presence of SMD was positively correlated with the presence or absence of vestibular dysfunction (Jacob, Furman, Durrant, & Turner, 1996). Furthermore, patients with agoraphobia showed a situational body sway pattern consistent with somatosensory dependence (Jacob, Furman, Durrant, & Turner, 1997). In addition, patients with anxiety disorders and SMD showed an unusual sensitivity to optic flow stimuli (Jacob, Redfern, & Furman, 1995).

In some patients with balance disorders, SMD becomes a major clinical focus. That is, the situational distress interferes significantly with the person's normal routine, to the extent that social, occupational or academic functioning is

Table 3
Proposed criteria for the diagnosis of SMP in the otoneurological setting, modeled after DSM-IV (1994)

All of the following are required:

(A) Marked and persistent fear that is excessive or unreasonable, cued by anticipation or presence of situations associated with intense vestibular stimulation, visual-vestibular/somatosensory mismatch or inadequate visual or somatosensory spatial cues.

(B) The symptom-provoking stimuli are avoided or else endured with intense anxiety or distress.

(C) The avoidance, anxious anticipation, or distress interferes significantly with the person's normal routine, occupational (or academic) functioning, or social activities or relationships, or there is marked distress about having the problem.

(D) Duration of 6 months or more.

(E) Pattern of distress is not better accounted for by an acute or severe balance disorder (e.g., acute labyrinthitis, bilateral vestibular hypofunction), or by a mental disorder, such as obsessive-compulsive disorder or post-traumatic stress disorder.

affected. The patients may develop avoidance behaviors to minimize vestibular symptoms. In these cases, we propose the term "SMP" as a diagnosis. Table 3 lists tentative diagnostic criteria for SMP. These criteria were developed in analogy with the DSM-IV criteria for Specific Phobia (American Psychiatric Association, 1994). Thus, whereas SMS is a construct and SMD is a symptom dimension, SMP represents a clinical diagnostic category. Patients with SMP are frequent in the otoneurological setting. The difference between SMD and SMP is analogous to the one between "fear of heights" and "height phobia." We will discuss SMP further below when describing "psychiatric overlay."

5. An otoneurological perspective on the interface between balance disorders and psychiatric disorders

Psychiatric conditions are common in otoneurological settings. Although anxiety disorders are particularly common, other psychiatric conditions are encountered as well. Fig. 1 illustrates that the interface between psychiatric and balance disorders spans all four categories of dizziness etiologies. Thus, the presence of a psychiatric disorder does not "rule out" a balance disorder. Patients with dizziness may have a balance disorder, a psychiatric disorder, both a balance disorder and a psychiatric disorder, or neither a balance disorder nor a psychiatric disorder. Fig. 3 illustrates a framework for understanding the overlap and interaction between psychiatric disorders and balance disorders from the perspective of the otoneurological clinician.

5.1. Psychiatric dizziness (Fig. 3A)

In this category belong those patients whose dizziness can be explained by their psychiatric disorder. Specifically, we have argued that the label "psy-

Fig. 3 Framework for interface between balance disorders and psychiatric disorders. The interface between balance disorders and psychiatric disorders is depicted as several levels of interaction ranging from noncoexistent disorders to a complete overlap in pathophysiology. (A) Psychiatric disorder without a balance disorder. (B) Balance disorder without a psychiatric disorder. (C) Cooccurrence of a psychiatric disorder that does not provoke dizziness and a balance disorder with no functional overlap. (D) Cooccurrence of psychiatric dizziness and balance disorder with no functional overlap. (E) Psychiatric overlay. (F) Behavioral/psychological modulation. (G) Neurological linkage.

chiatric dizziness" should be reserved for those patients in whom the dizziness (1) is part of a recognized psychiatric syndrome (e.g., the dizziness during a panic attack or the abnormal gait of conversion hysteria) and (2)

cannot be explained by vestibular dysfunction (Furness & Jacob, 1997). Examples of dizziness in psychiatric conditions that are not due to a balance disorder include abasia in conversion hysteria, poor concentration in depression (sometimes described as swimming sensations), and hyperventilation-induced lightheadedness during panic. With respect to patients with panic disorder, we have found that dizziness during a panic attack was uncorrelated with the presence or absence of vestibular dysfunction; dizziness between panic attacks, however, did predict vestibular dysfunction (Jacob et al., 1996b). Thus, according to our definition, dizziness occurring during a panic attack would be labeled "psychiatric dizziness," whereas dizziness between panic attacks would not. This conclusion is consistent with our clinical impression that many patients with panic disorder can learn to discriminate between two types of dizziness, i.e., psychiatric dizziness and nonpsychiatric dizziness (Beudel & Horak, this miniseries).

5.2. No functional overlap, chance concurrence (Fig. 3C and D)

In this category belong those patients who have both a psychiatric and balance disorder that are not functionally related, i.e., occur independently. Fig. 3C represents an individual with a balance disorder in whom the psychiatric disorder does not cause any dizziness, whereas Fig. 3D represents an individual with psychiatric dizziness (see above) who also has an independent balance disorder. That medical disorders and psychiatric disorders can co-occur should be a trivial consideration. Clearly, compared to psychiatrically healthy individuals, psychiatric patients are equally or more vulnerable to having a medical disorder. In medical settings, however, there may be a tendency automatically to attribute unexplained medical symptoms to psychiatric (psychogenic) origin, particularly if the patient also shows psychiatric symptoms.

5.3. Psychiatric overlay (Fig. 3E)

In this category, we include patients with balance disorders whose balance complaints seem out of proportion to the extent of the vestibular lesion, with respect to either intensity or chronicity. Additionally, the patients often show affective symptoms, either of anxiety or depression. The patients with SMP discussed earlier belong in this category. We conceptualize this area of overlap as involving poor coping with balance disorders, for example, excessive immobilization or avoidance after an acute vestibular disorder.

Brandt, Huppert, and Dieterich (1994) described a condition labeled "phobic postural vertigo" that fits within our diagnostic criteria for SMP. Patients with phobic postural vertigo complain of postural imbalance, as well as anxiety in certain situations, and they are excessively preoccupied with and disabled by their balance symptoms. More often than not, a personality disorder is the root

cause of the dysfunctional coping behavior. In patients with phobic postural vertigo, obsessive compulsive personality disorder was particularly common (Brandt et al., 1994). Similarly, it is our experience that most patients with SMP referred for psychiatric evaluation have compulsive personality disorder or traits.

5.4. Psychological/behavioral mediation (Fig. 3F)

The concept of psychological/behavioral mediation was developed to explain the apparent close relationship between certain anxiety disorders and vestibular dysfunction. This category of psychiatric/balance interactions differs from the preceding one (i.e., the level of psychiatric overlay) in that there may be no obvious balance symptoms, although there is an increased probability of clinical vestibular test abnormalities. In a study examining vestibular function in patients with pure panic disorder, panic disorder with agoraphobia, nonpanic anxiety disorders, or depression without anxiety, and normal controls, Jacob et al. (1996b) found vestibular dysfunction to be particularly common in the group of patients with panic disorder and agoraphobia. Both somatopsychic and psychosomatic causative relationships may be involved.

5.4.1. Somatopsychic effects of balance dysfunction

Somatopsychic relationships may be mediated through nonverbal "conditioning" or through verbal, "cognitive" processes (Barlow, 1988; Clark, 1986). At the onset of a balance disorder, intense vestibular symptoms may represent an unconditioned aversive stimulus. Thereafter, even relatively mild vestibular sensations may elicit panic as a result of interoceptive conditioning. Because of the situational specificity of vestibular symptoms, agoraphobia may then develop as learned avoidance behaviors. According to the cognitive somatopsychic mechanism, vestibular sensations induce panic because patients catastrophically interpret vestibular sensations as implying immediate danger. The somatopsychic effect of abnormal vestibular sensations may be particularly likely to occur in individuals already predisposed to developing panic disorder (e.g., those with a family history of panic disorder). Once established, panic disorder can persist even after resolution of the original balance disorder. For example, through further interoceptive conditioning, physical sensations other than vestibular sensations may acquire panic-triggering capabilities. Furthermore, agoraphobic avoidance behaviors may persist because successful avoidance prevents the unlearning of avoidance behaviors, regardless of their original cause.

5.4.2. Psychosomatic effects

It is well known that the gain of the vestibular/ocular reflex decreases with somnolence and increases with arousal. Therefore, increased anxiety may affect

vestibular function. Similarly, hyperventilation may affect vestibular responses (Theunissen, Huygen, & Folgering, 1986). Yardley and Rodfern (this miniseries) discuss psychosomatic effects in further detail. Psychosomatic mechanisms may play a clinical role especially in individuals with a history of a vestibular disorder who have become asymptomatic as a result of central compensation. Possibly, increased arousal and hyperventilation associated with anxiety might alter central vestibular compensatory processes and cause "decompensation," i.e., a reemergence of vestibular symptoms.

*5.5. Linkage (Fig. 3*g*)*

The neurological linkage model grew out of attempts to examine the neural circuitry that might be involved in generating symptoms of both an anxiety disorder and a balance disorder. This model is discussed in detail in Balaban and Thayer (this miniseries). The neurological linkage model raises the possibility that in some patients, both anxiety and balance symptoms are caused by an underlying central nervous system disturbance. Suggestive of such a linkage is the fact that vestibular dysfunction and migraines are related (discussed above) and patients with migraines also have a higher probability of panic disorder (Stewart, Brustau, & Keck, 1994; Stewart, Linet, & Celentano, 1989).

6. Unresolved issues

There are several unresolved issues regarding the taxonomy of dizziness and anxiety in the otoneurological setting. An area that is particularly poorly understood and not discussed in this paper is the influence of time course of the disease process. Some patients appear to develop an anxiety disorder without a clinically obvious prior or concurrent balance disorder, although they actually may have had a balance disorder in the more distant past. In this paper, we propose diagnostic criteria for SMP. However, the reliability of this diagnosis is yet to be established. Another area that is poorly understood is why some individuals develop SMP, others merely have SMD or SADS, and in still others, the symptoms are not situation specific at all. Further research is necessary to help understand these issues. Otoneurology as a medical field is still evolving and the clinical nomenclature is in flux. In particular, operational criteria for specific balance disorders modeled after DSM-IV have not yet been developed. As more data become available, clinical categories such as those in Fig. 3 may change.

Subject: Wind turbines noisy, says Vermont neighbor

... notice the testimony of a Vermonter in the "Heartland Institute" article, below (excerpted here):

Garry Degray, who already has wind turbines within sight of his property, warned at the meeting about the sight and noise pollution associated with industrial wind farms.

"Not only do I have a visual impact in my backyard, I'll have to listen to the industrial rumble of the windmills," said Degray at the hearing, according to the August 4 *Bennington Banner*. "Contradictory to their claims of a light swooshing noise, it's an industrial rumble. My quality of life is taking a nose dive."

Sut, by golly, Noh!n and Zikha tell us theyre totally quiet. "Go to Fenner and see for yourself!"

Wind Farm Proposed for Vt. National Forest

Author: James M. Taylor
 Published: The Heartland Institute 10/31/2005

A French-owned power company has announced plans to transform portions of Vermont's Green Mountain National Forest into an industrial wind farm if its development proposal receives the approval of the U.S. Forest Service.

The company, Deerfield Wind, cleared the first hurdle in mid-July when the Forest Service accepted a special use application for the proposed project.

Environmental activists have opposed virtually all resource development and road building in national forests. However, with environmental activists split on whether wind farms benefit or harm the environment, the French company is hoping for officials' acquiescence in developing the most pristine areas of the Green Mountain National Forest.

Mountain-top Ridges Threatened

According to the company's plan, 20 to 30 giant wind turbines—each taller than the Statue of Liberty—will be constructed on an 80-acre wind farm at the peak of some of the nation's most scenic and previously unspoiled mountains. In justifying the development, the company argued the industrial wind complex will power up to 18,000 local homes, at less than half the price of current energy sources.

The Forest Service must prepare an environmental impact statement and take into consideration public comments before deciding whether to approve the proposal.

Residents Protest

Many local residents protested the proposed wind farm at an August 3 community meeting held by the Forest Service at West Dover.

Garry Degray, who already has wind turbines within sight of his property, warned at the meeting about the sight and noise pollution associated with industrial wind farms.

"Not only do I have a visual impact in my backyard, I'll have to listen to the industrial rumble of the windmills," said Degray at the hearing, according to the August 4 *Bennington Banner*. "Contradictory to their claims of a light swooshing noise, it's an industrial rumble. My quality of life is taking a nose dive."

"It will provide us with very little energy," added Richard Joyce of Warington, as reported in the *Barnes & Noble* *Wilmington Times Argus* on August 4. "It will provide us with very little energy."

at a big price."

Newspaper on the Offensive

The Burlington Free Press, in a series of house editorials, authorized local sentiment against the industrial wind complex.

"Do we now want to see pristine ridge lines turned into production sites with enormous wind turbines whipping along the skyline?" asked a July 24 house editorial. "Most people support clean energy sources, but at what price? Is this the vision Americans had of its national forests when these wild places were set aside for our children and their children to enjoy?"

"There is a place for wind power in the clean energy mix, but pristine ridge lines that are home to important wildlife and other spectacular natural assets will not be the place for turbines," the editorial continued. "How much power will actually be generated by these towers, and is that amount worth the environmental degradation that can be expected? How viable are these towers, and at what distance? How noisy are the turbines?"

"Vermont's ridge lines, whether public or private, are the wrong place for sweeping, strobe-lighted monstrosities," added a July 27 house editorial. "The mountains are this state's backbone, home to wild animals and a like, quiet peace of solitude and contemplation for its people."

Easing Energy Prices?

"It's pretty apparent the price of oil is going up, we need to look at other sources of energy," countered Wilmington resident Gordon Ritter at the community meeting, as reported in the Bennington Banner.

Institute for Energy Research President Rob Bradley, however, said the price of oil has little to do with the economic costs and benefits of wind power. "Oil is used primarily for automobiles, while wind turbines are used by power plants. Coal, the primary fuel for power plants, is much cheaper than wind power."

In highlighting New York, the New York State Public Service Commission this month will begin charging electricity customers a 0.1 to 2.2 percent surcharge on their bills and handing it over as a subsidy to power companies who would otherwise balk at the high price of supplying wind power.

"In addition to the significant environmental impacts of the wind farm and necessary transmission lines, all for unreliable power—the Forest Service, environmentalists, and local residents should all be aware that this scheme exports jobs to Europe and India, where the majority of the world's wind turbines are built—and not using one stick of U.S. lumber," said Tom Tanton, a senior fellow at the Institute for Energy Research.

"Further," added Tanton, "since there isn't any oil used to generate electricity in the U.S., this scheme will not affect gasoline prices now or in the future and does nothing for our energy independence nor economic productivity."

James M. Taylor (jtaylor@heartland.org) is managing editor of Environment & Climate News.

COUPLE HIT BY WINDS OF CHANGE

Published on Friday, September 9th 2005

By BRIAN TILLEY

A COUPLE are on the verge of quitting the farm their family has occupied since 1860 rather than live in a forest of windmills.

But as they contemplate their future at Cornhill Farm at Kirkwhelpington, Richard and Lorna Thornton have fired a parting shot at their neighbours for agreeing to have a potential 117 windmills on their land.

"I'm absolutely disgusted that they have agreed to be party to the desecration of the Wanneys," said Mrs Thornton.

"We are the only landowners in the whole area who have turned down the offers from the developers."

There are proposals for four different windfarms in the Wanneys area, following its identification by the Government as a favoured site for wind power.

If they go ahead, there would be around 117 masts, each nearly 400 feet high covering much of the unspoilt landscape.

Most landowners in the area are happy to go along with the scheme, for they will be entitled to payments of £5,000 to £8,000 per windmill per year.

But Mr and Mrs Thornton have rejected approaches by the wind farm developers, despite the income it would guarantee.

Mrs Thornton said: "People think these windmills will be like the ones at Kirkheaton, but those are tiny by comparison,

"What is being proposed is 117 massive towers, nearly 400 feet high, and they will run the whole area."

The couple are actively considering leaving the farm, for the sake of Mr Thornton's health.

Mrs Thornton said: "He has a genuine phobia about windmills, and cannot pass the windfarm at Soutra (on the way to Edinburgh) without becoming ill.

"He just could not cope with all these mills, especially as six of them would be right in front of our house.

"It would be heartbreaking to leave after nearly 150 years, but we may have no choice,

"I can't believe the other landowners are going along with this."

Mrs Thornton questioned the need for the windfarms, pointing out the three windmills at Kirkheaton, some seven miles away, were hardly ever operating.

Similarly, the turbines at Blyth had been out of action for some time, and little effort was being made to repair them.

She said: "I think it's dishonest for the developers to say they are needed, when it seems they are not."

She was deeply concerned that the final say on whether the turbines were built rested not with either Tynedale or Northumberland County Council, but directly with the Department of Trade and Industry.

He said: "Local people aren't really going to have any say; the matter has been taken out of our hands," Comment # 266

He said the prospect of the turbines was already having an effect on property values in the Wannocys, with at least one house sale falling through as a direct result on the proposals.

He said: "Property prices are going to plummet, and it's affecting business too.

We do bed and breakfast here, and clients we have contacted have said they will not be back if the wonderful view becomes concrete jungle."

He also pointed out that the area was home to a rich variety of wildlife, including bats, owls and English crayfish, all of which could be affected by the development.

Representatives of one of the developers, the Banks Group, were meeting members of Kirkwhelpington Parish Council on Wednesday to expand on the proposals.

To Interested Parties:

I would like to share the realities and impacts that are being faced and continue to be faced by living near a wind turbine facility and hope to clear up some of the misconceptions and comparisons of the "so-called" progress regarding this particular industry.

I live within less than a 1-mile range from the Meyersdale Wind Turbine Facility in Somerset County, Pennsylvania.

I would like to share, from an up-close and personal experience, I guess one could label it the "Human Experimental Factor", the multiple nuisances and issues that coincide with these particular industrial turbine utilities that affect my neighbors, my family, local adjacent property owners and residents have and continue to experience over the past two years.

Prior to the building of the facility, our neighbors and we were never made aware of the nuisances that occur with a wind turbine facility. The noises emitted from the turbines have definitely changed our style of living. The noises produced from the blades turning on the turbines create a "threshing" sound within and around our home as well as the adjacent properties residing within certain geographical ranges of this facility.

At times it is difficult to fall asleep with the "pounding" of the turbines. One is often awakened by the "droning" noise of the turbines, finding it most difficult to fall back asleep. The noise becomes so disruptive; one can concentrate on nothing else but the constant droning. During the winter months, the noise is quite unbearable at times, sounding like drums beating constantly in the background. Sometimes the sound can be correlated to constant jet aircraft flying overhead. During the summer months, we cannot have our windows open to enjoy the fresh air or listen to the sounds of nature-just the noise created by the turbines. Advocates for these facilities will often compare this "threshing" noise to the "peaceful" sound of waves beating against the rocks at the seashore; but I have been to the seashore and it certainly is in no way comparable to the "calming sound" of waves. (I guess we are now just supposed to close our eyes and pretend we are at the ocean!) We are no longer able to enjoy peaceful picnics, hikes, and overnight camping upon the hill because of the noise nuisance, flickering and strobing of lights, and ugly view shed of the turbines. How sad it is to know that some of these rural farms and properties that have been intended to be passed down from family generation to family generation have to endure these nuisances.

Karen Ervin
Meyersdale, PA

Page 2 of 3

March 7, 2006

We should have learned from other countries mistakes regarding extensive turbine erection all over the landscapes. Upon sole opinion and opinion only-I know though, it is a "who knows who" and a "who will benefit from what (amount of money)" mentality. Hey, let's face it, if it is not in my back yard and I don't have to put up with it; I could care less about those who are being directly and indirectly affected. If it hurts bats, who cares! How sad it is that one does not fully understand the benefits of our environment and any particular species and/or plant life. There is a particular reason for all, brush up on the facts. One may also want to inquire why particular facilities do not and will not allow any on-going studies of avian species to proceed? Is there something to hide? Remember next it may be who cares about you, your family, your friends, and your neighbors. Let's not worry about whom and how it negatively effects them; let's just make some money! Quite a lot to ponder. Perhaps one may want to CAREFULLY inquire exactly how much these companies do pay in federal, state, and local taxes and how much revenue and credits they reap. Who exactly benefits and how much? It is quite astonishing!

Placement of these particular facilities is another issue that should be carefully studied before erecting them for those tax credits. From experience, computer regurgitated data cannot be taken into consideration for these particular projects. Topography is very important and has to be studied carefully in correlation to differential wind speeds, climatic conditions, and noise levels. One size does not fit all. As property owners whom have resided a numerous amount of years -some 50 plus; before this facility was built, and who have chosen to reside within a peaceful environment, we were never given the opportunity or made aware of the nuisances produced by this type of industrial facility. We were never given a chance to look at a waiver to choose if we wanted to live near this nuisance or explained the possible devaluation of property due to view -shed, noise, water run off etc.

We have experienced more power outages and surges; as well as excessive water run-off from the clear cut ridge top-Glade City was flooded with an enormous amount of water run-off from Hurricane Ivan-photographs and video footage clearly define where the water came from, disruption of portable phones within home and television reception, shadow flicker nuisances while driving on the local roadway and reported at a local Rod and Gun Club, a blinding white strobe light that was malfunctioning on one of the large turbines, and during daytime-close adjacent property owners disrupted by strobes.

One cannot understand that within larger municipalities and cities, noise nuisances and other issues created by those to others are liable for the disruptions. Shouldn't parties involved with this particular industry have to be held responsible and uphold stringent regulations and ordinances like any other industry? Just because we live in the rural countryside and have so for the majority of our lives and want our children to enjoy the peaceful countryside, why should we be the ones to suffer with such nuisances?

Employment by this particular industry is limited. Yes, local individuals may be employed while the facility is under construction, but in the end--well, look at the numbers--only a few are permanently employed. A slap in the face to a boost in the local economy. Look into the number of local individuals actually employed, the pay scale, and the amount of money the facility actually pays in taxes to the community, local, state, and federal governments. Where does the electricity go-is it utilized for local and surrounding areas with no charge? Who in particular is reaping the benefits from your local community? Exactly how much electricity do these particular facilities produce and in comparison to other sources of clean energy what percentage, the cost per kilowatt-hour, and how much maintenance do these structures require? These are just a few of the questions that need to be asked.

Ask the companies to thoroughly explain and to publicly share the clauses that are built into their legal documents between themselves and the landowners. It can be described as a "buyer beware" clause. Can be quite interesting reading, you may want to have your own legal expert with you before signing-the wording is quite creative and meanings quite crafty. I am sure those particular clauses do not want to be shared publicly. Careful, one may be giving up an abundance of rights regarding who is and who is not liable for the very nuisances and issues that these companies insist that the turbines do not create, such as noise, shadow flicker, strobe issues, right of road ways, water issues, and yes, even having the right to determine whether you are entitled to utilize your very own property as you see fit regarding varied farming, building, and recreational usage!

Stringent criteria, federal, state, and local laws, regulations and on-going long-term pre-post studies should be implemented and enforced prior to and during the operation of these industrial facilities. These industrial facilities and the parties involved who chose to have them erected should be held liable and accountable for any detrimental impacts and nuisances imposed and continue to be imposed upon humans and the environment. The facts should be carefully studied regarding this particular issue.

Remember we must work hand in hand to preserve what God has given us, to be greedy and to want to accomplish the goal of making a quick dollar at the expense of everyone and everything else is selfish. We need to take care of what we have now, not only for our future but also for the future generations that will follow.

This industry without stringent regulations can be truly labeled a "Pandora's Box". Be careful for what is opened, and be prepared for the negative impacts that have occurred and continue to occur with this industry.

Sincerely,

Karen Ervin

February 13, 2005

13 February 2005

Dear Sir:

I am writing to you in regards to living near an industrial power wind turbine facility. This facility is located in Somerset County near Meyersdale, Pennsylvania. The facility has been operating since December 2003.

Since this facility has been up and running, my family and I have experienced noise nuisance issues, specifically when trying to go to sleep at night. The noises are greater during the winter months. The noise appears to correlate to a continual droning sound. When awakened at night, there are times that is impossible to get back to sleep due to the thrashing sounds produced by the wind turbines. After the first few weeks of the initial operation, I began to experience difficulty with sleeping patterns. My family physician was consulted regarding this issue with difficulties falling asleep. I was prescribed sleeping medication.

The noise nuisance issue continues to exist. February of 2003, I was in my yard running my chain saw and the drone of the wind turbines could be heard over the sound produced by the chain saw. I was never made aware of any type of noise nuisances produced by these industrial turbines prior to their construction.

My lifestyle has changed since this operating industrial facility was erected within near vicinity of my residence. I fear that my real estate value has decreased due to the noise nuisance and deterioration of the scenic mountain ridges that surround my residence.

These industrial facilities and landowners should be held accountable and liable for any all nuisances that affect local and adjacent property owners.

Sincerely:

Rodger A. Hutzell Jr.

**Section title: Health effects of industrial low frequency noise, with scientific
& clinical documentation**

Health Effects of Wind Turbine Noise

Nina Pierpont, MD, PhD

(www.ninapierpont.com)

March 2, 2006

Industrial wind turbines produce significant amounts of audible and low-frequency noise. Dr. Oguz A. Soysal, Professor and Chairman of the Dept. of Physics and Engineering at Frostburg State University in Maryland, measured sound levels over half a mile away from the Meyersdale, PA, 20-turbine wind farm. Typical audible (A-weighted) dB (decibel) levels were in the 50-60 range, and audible plus low-frequency (C-weighted) dB were in the 65-70 range.¹ 65-70 dB is the loudness of a washing machine, vacuum cleaner, or hair dryer.² A difference of 10 dB between A and C weighting represents a significant amount of low-frequency sound by World Health Organization standards.³

The noise produced by wind turbines has a thumping, pulsing character, especially at night, when it is more audible. The noise is louder at night because of the contrast between the still, cool air at ground level and the steady stream of wind at the level of the turbine hubs.¹ Thus nighttime noise travels a long distance. It has been documented to be disturbing to residents 1.2 miles away from wind turbines in regular rolling terrain,² and 1.5 miles away in Appalachian valleys.⁴

At night, the WHO recommends, the level of continuous noise at the outside a dwelling should be 45 dB or less, and inside, 30 dB or less. These thresholds should be even lower if there is a significant low-frequency component to the sound, they add – as there is for wind turbines. Higher levels of noise disturb sleep and produce a host of effects on health, well-being, and productivity.

The decibel is logarithmic. Increasing the dB level by 10 multiplies the sound pressure level by 10. Increasing the dB level by 20 multiplies the sound pressure level by 100 (and 30 dB multiplies by 1000, etc.). Thus the 65 dB measured day and night half a mile from the Meyersdale wind farm has a measured intensity 100 times greater than the loudest continuous outdoor nighttime noise (45 dB) recommended by the WHO.

Typical ordinances proposed or passed for NY State communities considering industrial wind turbines allow A-weighted noise levels of 50 dB and construction of turbines only 1000 ft. from dwellings. These ordinances meet neither WHO nor NYS DEC standards, especially compared to the very low ambient noise levels (with dB levels typically in the 20's) in rural NY.⁵

The health effects of excessive community noise are carefully documented in the WHO report with reference to scientific and medical literature. Effects relevant to wind turbines, in terms of dB levels and noise type, are paraphrased and summarized from this report:

- For people to understand each other easily when talking, environmental noise levels should be 35 dB or less. For vulnerable groups (hearing impaired, elderly, children in the process of reading and language acquisition, and foreign language speakers) even lower background levels are needed. When noise interferes with speech comprehension, problems with concentration, fatigue, uncertainty and lack of

⁷ NYS DEC. 2004. *Assessing and Mitigating Noise Impacts*

self-confidence, irritation, misunderstandings, decreased work capacity, problems in human relations, and a number of stress reactions arise.⁹

- Wind turbine noise, as described above and experienced by many turbine neighbors, is easily within the decibel levels to disturb sleep. Effects of noise-induced sleep disturbance include fatigue, depressed mood or well-being, decreased performance, and increased use of sedatives or sleeping pills. Measured physiologic effects of noise during sleep are increased blood pressure and heart rate, changes in breathing pattern, and cardiac arrhythmias.¹⁰ Certain types of nighttime noise are especially bothersome, the authors note, including those which combine noise with vibration, those with low-frequency components, and sources in environments with low background noise.¹¹ All three of these special considerations apply to industrial wind turbines in rural NY State. Children, the elderly, and people with preexisting illnesses, especially depression, are especially vulnerable to sleep disturbance.
- Noise has an adverse effect on performance over and above its effects on speech comprehension. The most strongly affected cognitive areas are reading, attention, problem solving, and memory. Children in school are adversely affected by noise, and it is the uncontrollability of noise, rather than its intensity, which is most critical. The effort to tune out the noise comes at the price of increased levels of stress hormones and elevation of resting blood pressure. The adverse effects are larger in children with lower school achievement.¹²
- What is commonly referred to as noise "annoyance" is in fact a range of negative emotions, documented in people exposed to community noise, including anger, disappointment, dissatisfaction, withdrawal, helplessness, depression, anxiety, distraction, agitation, and exhaustion.¹³ Numerous reports from neighbors of new industrial wind turbine installations document these symptoms. The percentage of lightly annoyed people in a population starts to increase at 42 dB, and the percentage of moderately annoyed at 57 dB.¹⁴

Low-frequency sound is also sensed as pressure in the ears. It modulates the loudness of regular audible frequencies, and is sensed as a feeling of vibration in the chest and throat.¹⁵ Neighbors of industrial wind turbines describe the distressing sensation of having to breathe in sync with the rhythmic thumps of the turbine blades, especially at night when trying to sleep.

The participants in noise studies are selected from the general population and are usually adults. Vulnerable groups of people are underrepresented. Vulnerable groups include people with decreased personal abilities (old, ill, or depressed people), people with particular diseases or medical problems, people (children) dealing with complex cognitive tasks such as reading acquisition, people who are blind or hearing impaired, fetuses, babies and young children, and the elderly. These people may be less able to cope with the impacts of noise exposure and at greater risk for harmful effects than is documented in studies. Attention needs to be paid to them when developing regulations and setback requirements for industrial wind turbines and other sources of annoying and debilitating noise.

Wind turbines also create moving visual disturbances, especially early and late in the day when the long shadows of moving blades sweep rhythmically over the landscape. That portion of the population which is susceptible to vertigo, unsteadiness, or motion sickness (including many children and a large proportion of the elderly) will be vulnerable to unsteadiness and nausea when subjected to this visual disturbance. People with seizure disorders are susceptible to triggering of seizures by the strobe effect of seeing the sun through the moving blades.

To protect the public health, it is critical that industrial wind turbines not be placed within a minimum of 1.5 miles of human dwellings (homes, hospitals, residential schools, nursing homes, prisons, etc.) or schools. In mountainous terrain the setback should be greater, especially in topography with long parallel ridges and valleys as in the Appalachians.

NINA PIERPONT M.D. PH.D.

March 9, 2006

Dear Town Board Member,

I am taking the liberty of sending you the text of my testimony in Albany before the NYS Assembly Energy Committee this past Tuesday (March 7th), summarized here:

Wind Turbine Syndrome

Testimony before the New York State Legislature Energy Committee, Hearing on the RPS

March 7, 2006

Nina Pierpont, MD, PhD

MD, The Johns Hopkins University School of Medicine, 1991
Ph.D. Population Biology, Princeton University, 1985
B.A. Biology, Yale University, 1977
Fellow of the American Academy of Pediatrics
www.ninapierpont.com

To recapitulate, there is in fact a consistent cluster of symptoms, the Wind Turbine Syndrome, which occurs in a significant number of people in the vicinity of industrial wind turbines. There are specific risk factors for this syndrome, and people with these risk factors include a substantial portion of the population. A setback of 1.5 miles from homes, schools, hospitals, and similar institutions will probably be adequate, in most NY State terrain, to protect people from the adverse health effects of industrial wind turbines.

Do, I implore you, take this 1.5 mile setback into consideration as you weigh the merits of industrial wind turbines in your township.

Sincerely,

A handwritten signature in black ink that reads "Nina Pierpont".

Wind Turbine Syndrome

Testimony before the New York State Legislature Energy Committee

March 7, 2006

Nina Pierpont, MD, PhD

MD, The Johns Hopkins University School of Medicine, 1991
PhD, Population Biology, Princeton University, 1985
BA, Biology, Yale University, 1977

I am here to talk to you today as a physician-scientist about a clinical phenomenon called Wind Turbine Syndrome. This is relevant to today's hearing because it critically affects implementation of the RPS (Renewable Portfolio Standard) in terms of the siting of industrial wind turbines. Current siting practices (which are solely industry-driven) disregard public health. The supervision of the legislature—of this committee—is needed to create siting standards to protect the citizenry, all the citizenry, including citizens who are rural, old, ill, impaired, and very young.

Federal agencies are trying to put the brakes on willy-nilly wind turbine construction, citing, for instance, wildlife issues. The GAO (Government Accountability Office) last fall told US Fish and Wildlife to get involved. The National Academy of Sciences in April 2005 initiated a 20-month study on environmental impacts whose final report is due in December this year. There also needs to be a focus on human health, and the state needs to step up to the plate in terms of regulation.

I live in Franklin County, the poorest in NY State. Two years ago, after passage of the RPS, wind energy companies showed up there in force, as they have in all the poor, rural parts of the state. They showed up with no controls whatsoever, unregulated by either the legislature or NYSERDA (New York State Energy Research & Development Authority). Our town boards, made up of farmers, teachers, corrections officers, etc., were told, "You guys handle this," by our state representatives. I got involved as a responsible citizen and physician. Over the last 1½ years I have done a lot of reading, research, and interviews. I have spoken at town board meetings and before the St. Lawrence County Legislature, and published alone or with my husband (a retired university professor) numerous editorials and letters to the editor in local newspapers. My focus has been health issues and to some degree wildlife, in which I also have credentials in my PhD.

I get a lot of stander and abuse from the wind salesmen. Their favorites are saying that my abundantly referenced and footnoted articles, like the one before you (note: a separate handout), have "no evidence," or that I think wind turbines cause mad cow disease. The latter smear came from a town meeting in Ellenburg, NY, in October 2004, when I presented information culled from the medical literature on possible effects of low frequency noise. This included a paper out of the UK linking low frequency sound to prion diseases by a complex and highly speculative mechanism. I was very clear how speculative it was, but apparently the concept of something being speculative was over their heads, including over the heads of wind salesmen in the room.

I am not for or against the RPS. I'm an intelligent person and I support renewable energy. I am not here to shoot down wind energy, which probably has its place, though that place is not near people's homes or near schools, hospitals, or other locations where people have to sleep or learn.

I would like to stress that these are not "farms." One doesn't "farm" wind any more than one "farms" water in a hydroelectric dam or "farms" neutrons in an atomic plant. These are large, industrial installations. They make large-scale, industrial noise. "Jet engines" is the most common description I hear in surveying people—a jet engine that doesn't go away and which you can't get used to.

A syndrome in medicine is a constellation of symptoms and findings which is consistent from person to person. Defining a syndrome is the first step in investigating any new disease. The symptom cluster has to make sense in terms of pathophysiology—there has to be a plausible mechanism in terms of how the body and brain work. Defining a syndrome, and making that knowledge available to the medical community, lets other doctors go from scratching their heads over weird presentations of illness which are coming through their offices, to being able to validate and name what is going on and start to do something about it. It also opens the door to epidemiologic studies to define prevalence and risk factors, which will guide prevention and treatment.

Describing and documenting symptoms is the province of physicians. So is research on the causes of diseases. Deciding whether people have significant symptoms is not within the expertise of engineers or specialists in acoustics, even when the symptoms appear to be caused by noise. We physicians appreciate the noise data which engineers provide, but this data has nothing to do with whether people have symptoms or not. One British acoustics expert, Dr. Geoff Leventhall, is especially outrageous in this regard, insisting that people "can't" have symptoms because turbines "don't," he says, produce low frequency noise. His fallback, for which he is well paid by the industry, is that people make up their complaints. But he's not trained to distinguish whether people are making up their complaints, or to know about the range of physical, psychiatric, and neurological symptoms people might have. A related point: the hallmark of a good doctor is one who takes symptoms seriously and pursues them until they are understood (and ameliorated). This includes symptoms related to the brain, our most complex organ—symptoms which may be neurologic, psychiatric, or physical.

Three doctors that I know of are studying the Wind Turbine Syndrome: myself, one in England, and one in Australia. We note the same sets of symptoms. The symptoms start when local turbines go into operation and resolve when the turbines are off or when the person is out of the area. The symptoms include:

- 1) Sleep problems: noise or physical sensations of pulsation or pressure make it hard to go to sleep and cause frequent awakening.
- 2) Headaches which are increased in frequency or severity.
- 3) Dizziness, unsteadiness, and nausea.
- 4) Exhaustion, anxiety, anger, irritability, and depression.
- 5) Problems with concentration and learning.
- 6) Tinnitus (ringing in the ears).

Not everyone near turbines has these symptoms. This does not mean people are making them up; it means there are differences among people in susceptibility. These differences are known as risk factors. Defining risk factors and the proportion of people who get symptoms is the role of epidemiologic studies. These studies are under way.

Chronic sleep disturbance is the most common symptom. Exhaustion, mood problems, and problems with concentration and learning are natural outcomes of poor sleep.

Sensitivity to low frequency vibration is a risk factor. Contrary to assertions of the wind industry, some people feel disturbing amounts of vibration or pulsation from wind turbines, and can count in their bodies, especially their chests, the beats of the blades passing the towers, even when they can't hear or see them. Sensitivity to low frequency vibration in the body or ears is highly variable in people, and hence poorly understood and the subject of much debate.

Another risk factor is a preexisting migraine disorder. Migraine is not just a bad headache; it's a complex neurologic phenomenon which affects the visual, hearing, and balance systems, and can even affect motor control and consciousness itself. Many people with migraine disorder have increased sensitivity to noise and to motion—they get carsick as youngsters, and seasick, and very sick on carnival rides. Migraine-associated vertigo (which is the spinning type of dizziness, often with nausea) is a described medical entity. Migraine occurs in 12% of Americans. It is a common, familial, inherited condition.

To keep our balance and feel steady in space, we use three types of input: from our eyes (seeing where we are in space), from stretch receptors in joints and muscles, and from balance organs in the inner ear. At least two of these systems have to be working, and agreeing, to maintain balance. If the systems don't agree, as in seasickness or vertigo, one feels both ill and unsteady. Wind turbines impinge on this system in two ways: by the visual disturbance of the moving blades and shadows, and by noise or vibration impacting the inner ear.

Other candidate risk factors for susceptibility to Wind Turbine Syndrome are age-related changes in the inner ear. Five percent (5%) of otherwise healthy people from age 57 to 91 experience dizziness, and 24% experience tinnitus or ringing. Damage to the ears or hearing from other causes, such as noise exposure, is also a potential risk factor.

Inner ear organs are closely linked, by proven neurological connections, to the brain systems which control mood, anxiety, and one's sense of well-being. Disturbing the inner ear disturbs mood, not because a person is a whiner or doesn't like turbines, but because of neurology.

Data from a number of studies and individual cases document that in rolling terrain, disturbing symptoms of the Wind Turbine Syndrome occur up to 1.2 miles from the closest turbine. In long Appalachian valleys, with turbines on ridge-tops, disturbing symptoms occur up to 1.5 miles away. In New Zealand, which is more mountainous, disturbing symptoms occur up to 1.9 miles away.

In New York State, with its mixed terrain, I recommend a setback of 1.5 miles (8000 ft.) between all industrial wind turbines and people's homes or schools, hospitals, or similar institutions. This setback should be imposed immediately for turbines not yet built.

The legislature might want to set up a panel of clinicians to review the data and medical information I refer to here, but until this happens, and as research continues, a moratorium on all wind turbine construction within 1.5 miles of homes would be appropriate.

To recapitulate, there is in fact a consistent cluster of symptoms, the Wind Turbine Syndrome, which occurs in a significant number of people in the vicinity of industrial wind turbines. There are specific risks factors for this syndrome, and people with these risk factors include a substantial portion of the population. A setback of 1.5 miles from homes, schools, hospitals, and similar institutions will probably be adequate, in most NY State terrain, to protect people from the adverse health effects of industrial wind turbines.

Noisy Wind and Hot Air

Nina Pierpont, MD, PhD

As well as being about wind turbine noise, the discussion between North Country Advocates and Noble Environmental is about credibility, and the validity of information and the validity of sources. I'm going to address both of these—the wind turbine noise issue, and how to decide what and who to believe.

With regard to technical studies, *hired consultants are always less credible than university scientists who are free of industry ties.* Consider the pharmaceutical industry in this country: because the research on ill effects is done by companies selling the products, ill effects are concealed, and we end up with debacles like the recent one with Vioxx. Noble Environmental quotes in public what their paid consultant, Dr. Leventhall, says about my thoughts on wind turbine sound (or perhaps Noble just wrote it themselves, since some of the physics, "Synchronization effects can be reduced by running the turbines unsynchronized," is not worthy of a high school student). Professor van den Berg, a university researcher, replied the following to Noble when they asked him about my March 2 Telegram piece:

Indeed in the statement the term "low pitched thumping sound," a description of the sound character, seems to be equated to "low frequency noise," a technical term relating to a specific frequency range. The results of my investigations have not led to the conclusion that low frequency sound as such (implying sound of frequencies between 1 and approximately 200 Hz) are the likely cause of annoyance from modern wind turbines for most people. However, noise from (tall) wind turbines has not been addressed properly by wind turbine (farm) managers and consultants, and I can understand that residents who have become aware of that feel they have to further their arguments, but get confused by the technical jargon used in acoustics.

You may use this statement publicly, but only in its entirety (as I, NP, have done here).¹

Now let us read the summary of Prof. van den Berg's paper, "Do wind turbines produce significant low frequency sound levels?" presented in August 2004 at the 11th International Meeting on Low Frequency Noise and Vibration and Its Control, in which his answer is yes, they do, and this sound is significant, though its effect is indirect:

Wind turbines produce low frequency sounds, but it has not been shown this is a major factor contributing to annoyance. Sound from wind turbines involves several sound production mechanisms related to different interactions between the turbine blades and the air. Low frequency sound is predominantly the result of the displacement of air by a blade and of turbulence at the blade surface.

An important contribution to the low frequency part of the sound spectrum may be the result of the sudden variation in air flow the blade encounters when it passes the tower: the angle of attack of the incoming air suddenly deviates from the angle that is optimized for the mean flow.

This effect probably has not been considered important, as the blade-passing frequency is of the order of one hertz (one beat per second), where human hearing is very insensitive. This argument, however, obscures a very relevant effect: the low blade-passing frequency modulates well-audible (easily heard) higher frequency sounds and thus creates periodic sound. This effect is stronger at night because, in a stable atmosphere, there is a greater difference between rotor-averaged and near-tower wind speed. Measurements have shown that more turbines can interact to further amplify this effect.

The effect is confirmed by residents near wind turbines who mention the same common observation: often late in the afternoon or in the evening the turbine sound changes to a more "clapping" or "beating" sound, the rhythm in agreement with the blade-passing frequency. It is clear from the observations that this is associated to (with) a change to a higher atmospheric stability. The increased annoyance has not been investigated as such, although there are indications from [the] literature [that] this effect is relevant. It is of increasing relevance as the effect is stronger for modern (that is: tall) wind turbines.²

The university researcher (van den Berg), unlike Noble's paid consultant (Leventhall), states that the true noise issues are *not* being adequately addressed by wind farm developers or their consultants, and that wind turbines, contrary to what Noble is stating in its current public relations blitz, do produce low frequency sound. Van den Berg is investigating the complex way in which the low frequency vibrations of the blades passing the tower modify higher frequency sounds to produce the clapping or thumping noise that people even at some distance from wind turbines actually hear and complain about. In choosing what to investigate, he keeps his eye on what people are really experiencing.

What is significant about this research, too, is its discovery that taller turbines are louder than smaller ones, and its explanation of why wind turbines in general are so much noisier, at greater distances, than predicted by older sound propagation models. The answer is in the wind flow patterns higher above the ground, especially at night.³ Van den Berg studies turbines with 328 ft. hub height. Even according to Noble's consultant, Leventhall, the older predictions for how sound will carry apply only up to about 180 ft. hub height, while the turbines proposed for Malone will be 265 (and possibly 390) ft. at the hub. Thus the constant refrain of the Noble salesmen, "The new technology won't have this problem...this study does not apply...that study does not apply..." is contradicted by university research published in peer-reviewed journals.

Given all this argument, and the slowness with which research catches up to people's experience, how do we keep neighbors' needs for peace and quiet from being swept under the carpet?

One way is not by trusting the pre-construction "study" of sound commissioned by Noble. This will not actually be a study (since the turbines will not be up). At worst it could be a generalized piece of writing with no mention of local conditions or terrain at all, like the report prepared by the same consultant (Leventhall) for a wind power developer in New Zealand last year.⁴ At best it could be an exercise in modeling sound transmission over complex terrain in variable weather conditions, in a field of study in which the models themselves are in flux, changing as new information becomes available from existing wind farms. How will you and I, in Malone, be able to judge whether the models and variables are accurate and yield good results? We won't, of course, but we can be quite confident that a paid consultant will never reach the conclusion, for his client, that they can't go ahead with the project.

As an example of Noble's approach to the issue of pre-construction studies, let's turn to bird populations. This is my area of expertise, in which I have a PhD and scientific papers published in this country and abroad. The Noble representatives tell us that full and appropriate studies of bird and bat populations will be done before any turbines are erected. If this were truly Noble's intention, researchers would be in the field now, and Noble would not be talking about any turbine construction before 2007.⁵ Since there are no researchers in the field on the south end of Malone, and the main season for bird studies is well under way, we are really talking about 2008 at the earliest, because two years of study through the whole seasonal cycle—summer plus the spring and fall migrations (which extend from mid-March to December)—are a minimum requirement. Of course, the less you study something, the less chance you have of actually finding out something which might slow down the project.

Since this is the nature of Noble's approach to bird studies, I suspect their approach in other areas, such as noise, aesthetics, hydrology, soil, economic impact, etc., will be similar.

How can we prevent this, and have recourse if the turbines are actually built? Both problems require a tough, well-written town ordinance, specifying how studies are to be conducted and their results reviewed before permits are issued and, for later recourse, an escrow fund or cash bond to be put up by the developers, also before permits are issued. The escrow fund should be managed by a community committee, and set up to provide as many forms of economic safety for the community as are allowed by law. In it there needs to be a decommissioning fund for each turbine, to take it down, remove the concrete footer, and restore the land to its original state at the end of the turbine's useful life. There need to be funds to cover damages to the health, property values, and quality of life of nearby residents, should these occur. It would be good, too, if we could protect the town against future unfavorable changes in state tax law which might allow wind turbines to escape local taxation altogether, as they did in the State of Kansas.⁶ Wind energy companies have influence over tax law in both Washington and Albany, and there is already a New York State law on the books saying wind turbines are not subject to local taxes unless overridden by a specific local ordinance. Obviously, this override needs to be in our ordinance.

A powerful town ordinance has already been written for us by a group of lawyers. My husband, Calvin Luther Martin, circulated a preliminary version to the Malone Planning Board and Malone Town Board over a month ago, but it has now been refined and given a strong legal basis, anchored in the existing Malone Town Code. I urge townspeople to support a 6-month moratorium during which these issues are reviewed with the help of experienced outside counsel, followed by adoption of a strong regulatory ordinance that keeps our town and natural beauty from becoming another of civilization's waste heaps.

Wind power issues

To the editor:

I write in response to an article written by Denise Raymo which appeared 4/23/05 in the Press Republican, wherein my husband (Calvin Luther Martin) and I were interviewed about wind power. Since many folks read both the PR and the Telegram, and since the issues raised by Ms. Raymo's article impact our area significantly, I am submitting this letter to the Telegram.

A few quick clarifications: I am a pediatrician, not a psychologist. Second, the noise made by wind turbines is not constant; neighbors say it may be constant for days on end, and then the noise disappears for awhile.

With regard to mad cow disease: neither my husband nor I say that sound of any sort or turbines of any variety "cause" mad cow disease or any other prion disease. What we have said, and continue to say, is that there is a speculative paper in the medical literature laying out a hypothesis by which infrasound might be connected to prion disease (see Dr. Mark Purdey, *Medical Hypotheses*, 2003, vol. 60, no. 6, pp. 797-820). If we had not been widely misquoted by Noble Environmental in the first place (who were not even at the meeting where we brought this up) there would be no need to continue beating this dead horse (or cow).

With regard to low-frequency sound, I reviewed with Ms. Raymo a paper by the sound engineer G.P. van den Berg, a Dutch scientist ("Do wind turbines produce significant low frequency sound levels?" Eleventh International Meeting on Low Frequency Noise and Vibration and its Control, Maastricht, The Netherlands, 30 August to 1 September 2004, 8 pp.; contact g.p.van.den.berg@phys.rug.nl). Prof.

van den Berg's paper unequivocally documents the low-frequency sound produced by wind turbines.

Moreover, most of the sound energy produced by wind turbines is in the lower frequencies. What I told Ms. Raymo was perhaps too complicated to include in a newspaper article, but it is my answer to repeated Noble assertions that wind turbines "do not" create low-frequency sound. They do, and the low-frequency sound has an important role in creating the pulsating quality of wind turbine noise at night, which is one of its most troubling features (see van den Berg, "Effects of the wind profile at night on wind turbine sound," *Journal of Sound and Vibration*, 2004, vol. 277, pp. 965-970; go to <http://www.nowap.co.uk/docs/wind-noise.pdf> for a pre-publication copy).

Finally, I raised the issue of the Lincoln Township (Wisconsin) Wind Turbine Moratorium Survey not to provide evidence about low-frequency sound, but because Noble representatives are circulating the Survey's summary statistics here in Malone (and perhaps elsewhere) to refute data I used from the Survey's tables in my Telegram article of 3/2/05. The Survey asked people whether they were bothered by noise, flicker, lights and other issues during the first two years of wind turbine operation in 1999-2001. The summary statistics (which Noble is circulating) include all people who answered within two miles of the turbines. The data I quote break down these totals by distance from the turbines, so that we hear, for example, what people within half a mile are saying. Needless to say, the percentages complaining are higher closer to the turbines (e-mail me at ruehlon2@westolcom.com for a copy of the entire survey, or go to <http://www.giebemountaingroup.org/Articles/Lincoln120403.doc> for excerpts and comments).

NINA PIERPONT M.D. PH.D.

February 8, 2006

To whom it may concern:

I was contacted recently by Daniel & Carolyn d'Entremont of Yarmouth County, Nova Scotia (Canada), to ask for my assistance explaining a variety of ailments they and their six children have been suffering over the past year—over since 17 industrial wind turbines were built within a mile of their home (the nearest being 1000' away). (Incidentally, they found me by way of an article I published on the Internet a year ago on the health effects of wind turbines.)

The d'Entremonts and I had a lengthy phone conversation on February 4, 2006, wherein they described a variety of ailments that I recognized as being associated with long-term exposure to industrial low frequency noise. I assured them that their symptoms are no fabrication or illusion; they are genuine and confirmed by clinical literature.

In the interest of helping the d'Entremonts get these turbines turned off and getting these good people back into their home (which they are about to abandon), and back to good health, I offered to do a formal telephone interview, but this time to tape record it. The enclosed CD contains the recording of that interview, made with the d'Entremonts' permission both to make the recording and distribute it widely. Toward the end of the interview I offer my clinical judgment on their ailments.

The second enclosed CD contains photographs of the d'Entremont home showing the industrial turbines nearby. This CD has, in addition, photographs of the Fenner (New York) and Tug Hill Plateau (Lewis County, New York) windplants, illustrating the same problem: turbines sited far too close to people's homes. I can virtually guarantee that people in Fenner and on the Tug Hill Plateau who live within 1.5 miles of these turbines will suffer (or are suffering) from identical health effects described herein by the d'Entremonts. The medically irresponsible siting of turbines is not restricted to Nova Scotia, Fenner, and Tug Hill; it's a global problem.

I enclose, as well, a short report I did recently on the "Health effects of wind turbine noise" (2/4/06). This merely samples the literature on low frequency sound and strobing (from the propellers) impacting human health; I am happy to supply anyone, who wishes to see it, with further evidence from peer-reviewed scientific and clinical journals.

PERSONAL

Place of birth: Stamford, CT
 Date of birth: May 18, 1955
 Married with two grown stepchildren

EDUCATION AND TRAINING

Education

1991	M.D.	The Johns Hopkins University School of Medicine
1985	Ph.D.	Princeton University (Ecology, Evolution, and Behavior)
1981	M.A.	Princeton University (Ecology, Evolution, and Behavior)
1977	B.A.	Yale University (cum laude)
1973		Milton Academy, Milton, Mass.
1970		New Canaan Country Day School, Conn.

Post-Doctoral Training

1992 to 94	Pediatrics	Dartmouth-Hitchcock Medical Center, Lebanon, NH
1991 to 92	Pediatrics	Children's National Medical Center, Washington, DC
1985 to 86	Ornithology	American Museum of Natural History, New York, NY

Licensure and Certification

1997	Licensed Physician, New York
1997	Licensed Physician, New Hampshire (expired)
1995	Pediatric Advanced Life Support Instructor and Affiliate Faculty
1994	Diplomate, American Board of Pediatrics (recertified 2000, expires 2008)
1994	Licensed Physician, Alaska (expired)
1994	DEA Registration
1994	Advanced Trauma Life Support Provider
1994	Advanced Cardiac Life Support Provider
1992	Neonatal Advanced Life Support Provider

PROFESSIONAL APPOINTMENTS

Hospital or Affiliated Institution Appointments

10/00 to 12/03	Senior Attending in Pediatrics	Bassett Healthcare, Cooperstown, NY
1997 to 00	Attending Pediatrician	Alice Hyde Hospital, Malone, NY
1995 to 96	Chief of Pediatrics	Yukon-Kuskokwim (Yup'ik Eskimo) Delta Regional Hospital, Bethel, AK
1994 to 95	Staff Pediatrician	Yukon-Kuskokwim (Yup'ik Eskimo) Delta Regional Hospital, Bethel, AK

Other Professional Positions

2004 to ...	Private Practice (Solo) Behavioral Pediatrics	Malone, NY (poorest county in state)
1998 to 00	Private Practice (Solo) Pediatrics	Malone, NY (poorest county in state)
1997 to 00	Staff Pediatrician	St. Regis Mohawk (Iroquois) Health Services, Hogansburg, NY
1997 to 98	Staff Pediatrician	North Country Children's Clinic (clinic for needy children), Malone, NY

Academic Appointments

2000 to 03	Assistant Clinical Professor of Pediatrics	Columbia University College of Physicians and Surgeons
1980 to 85	Teaching Assistant	Princeton University
1978	Teacher	Children's School of Science, Woods Hole, MA
1977 to 78	Research Assistant	Yale University

LANGUAGES SPOKEN Spanish, FrenchAWARDS AND HONORS

1984	National Science Foundation Dissertation Grant (Princeton)
1979 to 82	National Science Foundation Predoctoral Fellowship (Princeton)
1979, 80	Dunlop Prize, Biology Department, Princeton University
1981 to 83	Research grants from the National Academy of Sciences, American Museum of Natural History, American Ornithologists' Union, and others
1973	National Merit Scholar to Yale University

MAJOR ADMINISTRATIVE RESPONSIBILITIES

1995 to 96	Chief of Pediatrics	Yukon-Kuskokwim (Yup'ik Eskimo) Delta Regional Hospital, Bethel, AK
------------	---------------------	---

PROFESSIONAL SOCIETY INVOLVEMENT

1997 to ... American Academy of Pediatrics Fellow

COMMUNITY SERVICE

1998 to 00 Physician member, Child Abuse Response Team, Franklin County, NY

Music Acoustics

What is a decibel?

And what are the different types of decibel measurement: dB, dBA, dBC, dBV, dBm and dBu? How are they related to loudness? (A related page allows you to measure your hearing response and to compare with standard hearing curves.)

- [Definition and examples](#)
- [Sound files to show the size of a decibel](#)
- [Standard reference levels \("absolute" sound level\)](#)
- [Logarithmic response, psychophysical measures, sones and phons](#)
- [Recording level and decibels \(dBV and dBm\)](#)
- [dBu and radiation](#)
- [Example problems using dB](#) for amplifier gain, speaker power, hearing sensitivity etc.
- [Related pages](#)
- [What is a logarithm?](#) A brief introduction.

Definition and examples

The decibel (dB) is used to measure sound level, but it is also widely used to electronics, signals and communication. The dB is a logarithmic unit used to describe a ratio. The ratio may be power, sound pressure, voltage or intensity or several other things. Later on we relate dB to the phon and the sone (other units related to loudness). But first, to get a taste for logarithmic units, let's look at some numbers. (If you have forgotten, go to [What is a logarithm?](#))

For instance, suppose we have two loudspeakers, the first playing a sound with power P₁, and another playing a louder version of the same sound with power P₂, but everything else (how far away, frequency) kept the same.

The difference in decibels between the two is defined to be

$$10 \log (P_2/P_1) \text{ dB} \quad \text{where the log is to base 10.}$$

If the second produces twice as much power than the first, the difference in dB is

$$10 \log (P_2/P_1) = 10 \log 2 = 3 \text{ dB.}$$

If the second had 10 times the power of the first, the difference in dB would be

$$10 \log (P_2/P_1) = 10 \log 10 = 10 \text{ dB.}$$

If the second had a million times the power of the first, the difference in dB would be

$$10 \log (P_2/P_1) = 10 \log 1000000 = 60 \text{ dB}$$

This example shows one feature of decibel scales that is useful in discussing sound: they can describe very big ratios using numbers of modest size. But note that the decibel describes a *ratio*: so far we have not said what power either of the speakers radiates, only the ratio of powers. (Note also the factor 10 in the definition, which puts the 'dec' in decibel).

Sound pressure, sound level and dB Sound is usually measured with microphones and they respond (approximately) proportionally to the sound pressure, p . Now the power in a sound wave, all else equal, goes as the square of the pressure. (Similarly, electrical power in a resistor goes as the square of the voltage.) The log of the square of x is just $2 \log x$, so this introduces a factor of 2 when we convert to decibels for pressures. The difference in sound pressure level between two sounds with p_1 and p_2 is therefore:

$$20 \log (p_2/p_1) \text{ dB} = 10 \log (p_2^2/p_1^2) \text{ dB} = 10 \log (P_2/P_1) \text{ dB} \quad \text{where again the log is to base 10.}$$

Sound files to show the size of a decibel

What happens when you halve the sound power? The log of 2 is 0.3, so the log of 1/2 is -0.3. So, if you halve the power, you reduce the power and the sound level by 3 dB. Halve it again (down to 1/4 of the original power) and you reduce the level by another 3 dB. That is exactly what we have done in the first graphic and sound file below.

The first sample of sound is white noise (a mix of all audible frequencies, just as white light is a mix of all visible frequencies). The second sample is the same noise, with the voltage reduced by a factor of the square root of 2. The reciprocal of the square root of 2 is approximately 0.7, so -3 dB corresponds to reducing the voltage or the pressure to 70% of its original value. The green line shows the voltage as a function of time. The red line shows a continuous exponential decay with time. Note that the voltage falls by 50% for every second sample.

Note, too, that a doubling of the power does not make a huge difference to the loudness. We'll discuss this further below, but it's a useful thing to remember when choosing sound reproduction equipment.

Sound files and flash animation by John Tann and George Hatzidimitris.

If this animation doesn't work, or if you want wav files, go to [No flash version](#).

How big is a decibel? In the next series, successive samples are reduced by just one decibel.

One decibel is close to the Just Noticeable Difference (JND) for sound level. As you listen to these files, you will notice that the last is quieter than the first, but it is rather less clear to the ear that the second of any pair is quieter than its predecessor. $10 \cdot \log_{10}(1.26) \approx 1$, so to increase the sound level by 1 dB, the power must be increased by 26%, or the voltage by 12%.

What if the difference is less than a decibel? Sound levels are rarely given with decimal places. The reason is that sound levels that differ by less than 1 dB are hard to distinguish, as the next example shows.

You may notice that the last is quieter than the first, but it is difficult to notice the difference between successive pairs. $10 \cdot \log_{10}(1.07) \approx 0.3$, so to increase the sound level by 0.3 dB, the power must be increased by 7%, or the voltage by 3.5%.

Standard reference levels ("absolute" sound level)

When the decibel is used to give the sound level for a single sound rather than a ratio, then a reference level must be chosen. For sound intensity, the reference level (for air) is usually chosen as 20 micropascals, or 0.02 mPa. (This is very low: it is 2 ten billionths of an atmosphere. Nevertheless, this is about the limit of sensitivity of the human ear, in its most sensitive range of frequency. Usually this sensitivity is only found in rather young people or in people who have not been exposed to loud music or other loud noises. Personal music systems with in-ear speakers ("walkmans") are capable of very high sound levels in the ear, and are believed by some to be responsible for much of the hearing loss in young adults in developed countries.)

So if you read of a sound intensity level of 86 dB, it means that

$$20 \log (p_2/p_1) = 86 \text{ dB}$$

where p_1 is the sound pressure of the reference level, and p_2 that of the sound in question. Divide both sides by 20.

$$\log (p_2/p_1) = 4.3$$

$$p_2/p_1 = 10^{4.3}$$

4 is the log of 10 thousand, 0.3 is the log of 2, so this sound has a sound pressure 20 thousand times greater than that of the reference level ($p_2/p_1 = 20,000$). 86 dB is a loud but not dangerous level of sound, if it is not maintained for very long.

What does 0 dB mean? This level occurs when the measured intensity is equal to the reference level, i.e., it is the sound level corresponding to 0.02 mPa. In this case we have

$$\text{sound level} = 20 \log (p_{\text{measured}}/p_{\text{reference}}) = 20 \log 1 = 0 \text{ dB}$$

So 0 dB does not mean no sound, it means a sound level where the sound pressure is equal to that of the reference level. This is a small pressure, but not zero. It is also possible to have negative sound levels: -20 dB would mean a sound with pressure 10 times smaller than the reference pressure, ie 2 micropascals.

Not all sound pressures are equally loud. This is because the human ear does not respond equally to all frequencies: we are much more sensitive to sounds in the frequency range about 1 kHz to 4 kHz (1000 to 4000 vibrations per second) than to very low or high frequency sounds. For this reason, sound meters are usually fitted with a filter whose response to frequency is a bit like that of the human ear. (More about these filters below.) If the "A weighting filter" is used, the sound pressure level is given in units of dB(A) or dBA. Sound pressure level on the dBA scale is easy to measure and is therefore widely used. It is still different from loudness, however, because the filter does not respond in quite the same way as the ear. To determine the loudness of a sound, one needs to consult some curves representing the frequency response of the human ear, given below. (Alternatively, you can measure your own hearing response.)

Logarithmic response, psychophysical measures, sones and phons

Why do we use decibels? The ear is capable of hearing a very large range of sounds: the ratio of the sound pressure that causes permanent damage from short exposure to the limit that (undamaged) ears can hear is more than a million. To deal with such a range, logarithmic units are useful: the log of a million is 6, so this ratio represents a difference of 120 dB. Psychologists also say that our sense of hearing is roughly logarithmic (see under sones below). In other words, they think that you have to increase the sound intensity by the same factor to have the same increase in loudness. Whether you agree or not is up to you, because this is a rather subjective question. (Listen to the sound files linked above.)

The filters used for dBA and dBC

The most widely used sound level filter is the A scale, which roughly corresponds to the inverse of the 40 dB (at 1 kHz) equal-loudness curve. Using this filter, the sound level meter is thus less sensitive to very high and very low frequencies. Measurements made on this scale are expressed as dBA. The C scale is practically linear over several octaves and is thus suitable for subjective measurements only for very high sound levels. Measurements made on this scale are expressed as dBC. There is also a (rarely used) B weighting scale, intermediate between A and C. The figure below shows the response of the A filter (left) and C filter, with gains in dB given with respect to 1 kHz. (For an introduction to filters, see [RC filters, integrators and differentiators](#).)

On the [music acoustics](#) and [speech acoustics](#) sites, we plot the sound spectra in dB. The reason for this common practice is that the range of measured sound pressures is large. We plot acoustic impedance spectra in dB for the same reason: the input impedance of a musical instrument, such as the flute, varies over a factor of several thousand.

Loudness, phons and sones

The **phon** is a unit that is related to dB by the *psychophysically measured* frequency response of the ear. At 1 kHz, readings in phons and dB are, by definition, the same. For all other frequencies, the phon scale is determined by the results of experiments in which volunteers were asked to adjust the loudness of a signal at a given frequency until they judged its loudness to equal that of a 1 kHz signal. To convert from dB to phons, you need a graph of such results. Such a graph depends on sound level: it becomes flatter at high sound levels.

Curves of equal loudness determined experimentally by Robinson & Dadson in 1956, following the original work of Fletcher & Munson (Fletcher, H. and Munson, W.A. (1933) *J Acoust.Soc. Am.* 6:59; Robinson, D.W. and Dadson, R.S.(1956) *Br. J. Appl. Phys.* 7:166. Plots of equal loudness as a function of frequency are often generically called Fletcher-Munson curves.)

The **sone** is derived from psychophysical measurements which involved volunteers adjusting sounds until they judge them to be twice as loud. This allows one to relate perceived loudness to phons. A sone is defined to be equal to 40 phons. Experimentally it was found that a 10 dB increase in sound level corresponds approximately to a perceived doubling of loudness. So that approximation is used in the definition of the phon: 0.5 sone = 30 phon, 1 sone = 40 phon, 2 sone = 50 phon, 4 sone = 60 phon, etc.

Wouldn't it be great to be able to convert from dB (which can be measured by an instrument) to sones (which approximate loudness as perceived by people)? This is usually done using tables that you can find in acoustics handbooks. However, if you don't mind a rather crude approximation, you can say that the A weighting curve approximates the human frequency response at low to moderate sound levels, so dBA is very *roughly* the same as phons. Then use the logarithmic relation between sones and phons described above.

Recording level and decibels

Meters measuring recording or output level on audio electronic gear (mixing consoles etc) are almost always recording the AC rms voltage (see links to find out about AC and rms). For a given resistor R , the power P is V^2/R , so

$$\text{difference in voltage level} = 20 \log (V_2/V_1) \text{ dB} = 10 \log (V_2^2/V_1^2) \text{ dB} = 10 \log (P_2/P_1) \text{ dB}, \text{ or}$$

$$\text{absolute voltage level} = 20 \log (V/V_{ref})$$

where V_{ref} is a reference voltage. So what is the reference voltage?

The obvious level to choose is one volt rms, and in this case the level is written as **dBV**. This is rational, and also convenient with modern analog-digital cards whose maximum range is often about one volt rms. So one has to remember to keep the level in negative dBV (less than one volt) to avoid clipping the peaks of the signal, but not too negative (so your signal is still much bigger than the background noise).

Sometimes you will see **dBm**. This used to mean decibels of electrical power, with respect to one milliwatt, and sometimes it still does. However, it's complicated for historical reasons. In the mid twentieth century, many audio lines had a nominal impedance of 600 Ω . If the impedance is purely resistive, and if you set $V^2/600 \Omega = 1 \text{ mW}$, then you get $V = 0.775 \text{ volts}$. So, providing you were using a 600 Ω load, 1 mW of power was 0 dBm was 0.775 V, and so you calibrated your level meters thus. The problem arose because, once a level meter that measures voltage is calibrated like this, it will read 0 dBm at 0.775 V even if it is not connected to 600 Ω . So, perhaps illogically, dBm will sometimes mean dB with respect to 0.775 V. (When I was a boy, calculators were expensive so I used dad's old slide rule, which had the factor 0.775 marked on the cursor window to facilitate such calculations.)

How to convert dBV or dBm into dB of sound level? There is no simple way. It depends on how you convert the electrical power into sound power. Even if your electrical signal is connected directly to a loudspeaker, the conversion will depend on the efficiency and impedance of your loudspeaker. And of course there may be a power amplifier, and various acoustic complications between where you measure the dBV on the mixing desk and where your ears are in the sound field.

dB_i and radiation that varies with direction

Radiation that varies in direction is called **anisotropic**: a source that emits sound (or something else) equally in all directions is called an **isotropic source**. When you want to emit in (or receive from) a particular direction, you want the ratio of intensity measured in that direction, at a given distance, to be higher than that measured at the same distance from an isotropic radiator. This ratio is called the **gain**; express the ratio in dB and you have the gain in dB_i for that radiator. This unit is mainly used for antennae, either transmitting and receiving.

Example problems

A few people have written asking for examples in using dB in calculations. So...

- An amplifier has an input of 10 mV and an output of 2 V. What is its voltage gain in dB?

Voltage, like pressure, appears squared to expressions for power or intensity. (The power dissipated in a resistor R is V^2/R .) So, by convention, we define:

$$\begin{aligned} \text{gain} &= 20 \log (V_{\text{out}}/V_{\text{in}}) \\ &= 20 \log (2\text{V}/10\text{mV}) \\ &= 46 \text{ dB} \end{aligned}$$

(In the acoustic cases given above, we saw that the pressure ratio, expressed in dB, was the same as the power ratio: that was the reason for the factor 20 when defining dB for pressure. It is worth noting that, in the voltage gain example, the power gain of the amplifier is unlikely to equal the voltage gain. The power is proportional to the square of the voltage in a given resistor. However, the input and output impedances of amplifiers are often quite different. For instance, a buffer amplifier or emitter follower has a voltage gain of about 1, but a large current gain.)

- All else equal, how much louder is loudspeaker driven (in its linear range) by a 100 W amplifier than by a 10 W amplifier?

The powers differ by a factor of ten, which, as we saw above, is 10 dB. All else equal here means that the frequency responses are equal and that the same input signal is used, etc. So the frequency dependence should be the same. 10 dB corresponds to 10 phons. To get a perceived doubling of loudness, you need an increase of 10 phons. So the speaker driven by the 100 W amplifier is twice as loud as when driven by the 10 W, assuming you stay in the linear range and don't distort or destroy the speaker. (The 100 W amplifier produces twice as many sones as does the 10 W.)

- If, in ideal quiet conditions, a young person can hear a 1 kHz tone at 0 dB emitted by a loudspeaker (perhaps a softspeaker?), by how much must the power of the loudspeaker be increased to raise the sound to 110 dB (a dangerously loud but survivable level)?

The difference in decibels between the two signals of power P_2 and P_1 is defined above to be

$$\Delta L = 10 \log (P_2/P_1) \text{ dB} \quad \text{so, raising 10 to the power of these two equal quantities:}$$

$$10^{\Delta L/10} = P_2/P_1 \quad \text{so:}$$

$$P_2/P_1 = 10^{110/10} = 10^{11} = \text{one hundred thousand million.}$$

which is a demonstration that the human ear has a remarkably large dynamic range, perhaps 100 times greater than that of the eye.

A FAQ

A few people have written asking for examples of sounds in dB or dB(A). How loud is an aircraft? A train? A person singing? A dog barking? A power tool? The answers to this question vary considerably. It depends strongly upon how far away you are, whether you are indoors or not, whether there is reverberation, how strong the particular source is and what its spectrum is. To give values, without being very specific about the conditions, would be somewhat misleading. Because the rest of this page is intended to be reliable, as far as it goes, I'd rather not give values here.

 [[Basics](#) | [Research](#) | [Publications](#) | [People](#) | [Home](#)]

What is a logarithm? A brief introduction.

First let's look at exponents. If we write 10^2 or 10^3 , we mean

$$10^2 = 10 \cdot 10 = 100 \text{ and } 10^3 = 10 \cdot 10 \cdot 10 = 1000.$$

So the exponent (2 or 3 in our example) tells us how many times to multiply the base (10 in our example) by itself. For this page, we only need logarithms to base 10, so that's all we'll discuss. In these examples, 2 is the log of 100, and 3 is the log of 1000. If we multiply ten by itself only once, we get 10, so 1 is the log of 10, or in other words

$$10^1 = 10.$$

We can also have negative logarithms. When we write 10^{-2} we mean 0.01, which is 1/100, so

$$10^{-2} = 1/100$$

Let's go one step more complicated. Let's work out the value of $(10^2)^3$. This is easy enough to do, one step at a time:

$$(10^2)^3 = (100)^3 = 100 \cdot 100 \cdot 100 = 1,000,000 = 10^6.$$

By writing it out, you should convince yourself that, for any whole numbers n and m,

$$(10^n)^m = 10^{nm}.$$

But what if n is not a whole number? Since the rules we have used so far don't tell us what this would mean, we can define it to mean what we like, but we should choose our definition so that it is consistent. The definition of the logarithm of a number a (to base 10) is this:

$$10^{\log a} = a$$

In other words, the log of the number a is the power to which you must raise 10 to get the number a. For an example of a number whose log is not a whole number, let's consider the square root of 10, which is 3.1623..., in other words

$$3.1623^2 = 10. \text{ Using our definition above, we can write this as } 3.1623^2 = (10^{\log 3.1623})^2 = 10 = 10^1.$$

However, using our rule that $(10^n)^m = 10^{nm}$, we see that in this case $\log 3.1623 \cdot 2 = 1$, so the log of 3.1623... is 1/2. The square root of 10 is $10^{0.5}$. Now there are a couple of questions: how do we calculate logs? and Can we be sure that all real numbers greater than zero have real logs? We leave these to mathematicians (who, by the way, would be happy to give you a more rigorous treatment of exponents than this superficial account).

A few other important examples are worth noting. 10^0 would have the property that, no matter how many times you multiplied it by itself, it would never get as large as 10. Further, no matter how many times you divided it into 1, you would never get as small as 1/10. Using our $(10^n)^m = 10^{nm}$ rule, you will see that $10^0 = 1$ satisfies this, so the log of one is zero. The log of 2 is used often in acoustics, and it is 0.3010 (see graph at right). Hence, a factor of 2 in power corresponds to 3.01 dB, which we should normally write as 3 dB because, as you can discover for yourself in [helping response](#), decimal points of decibels are usually too small to notice.

[Relativity](#) 1905 2005

Happy birthday, theory of relativity!

As of June 2005, relativity is 100 years old. Our contribution is [Einstein Light: relativity in brief... or in detail](#). It explains the key ideas in a short multimedia presentation, which is supported by links to broader and deeper explanations.

The Strange Case of Dr. Geoff Leventhall

by

Calvin Luther Martin, PhD
Associate Professor of History (retired)
Rutgers University
New Brunswick, NJ

2-25-06

There is a man named Dr. Geoff Leventhall from the United Kingdom who hires himself out to wind energy companies as a noise consultant -- the noise being from industrial wind turbines.

The interesting thing about this Leventhall is that he insists, in the face of clear evidence to the contrary, that industrial wind turbines produce no low frequency noise (basically, infrasound). So he wrote in the *Malone (New York, USA) Telegram* this past autumn, "I have always said ... there is no problem of infrasound from wind turbines" (p. 4). Earlier this month (February 2006) he was quoted in the *Hawke's Bay Today (New Zealand)* newspaper as saying, "I can state quite categorically that there is no significant infrasound from current designs of wind turbines."

Dr. Leventhall doesn't seem to know what he thinks. For when we turn to his May 2003 DEFRA (UK) "Review of Published Research on Low Frequency Noise and Its Effects," he writes: "Infrasound ... is common in urban environments, and as an emission from many artificial sources ... including wind turbines." Oops! Leventhall goes on: "The effects of infrasound or low frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficiency of many structures (dwellings, walls, and hearing protection) in attenuating low frequency noise compared with other noise" (p. 54). (Turn to the footnote back on p. 53 of the "Review" and we're told this section was "contributed by" Dr. P.L. Peimear. This does not let Leventhall off the ethical hook, however; as lead author he must take full responsibility for everything in his report.)

Like I say, Leventhall doesn't seem to know what he thinks. For that matter, it's not clear he and his co-authors do the thinking they take credit for. When we turn to Dr. Birgitta Berglund's "Sources and Effects of Low-Frequency Noise" in the *Journal of the Acoustical Society of America* (May 1996), we find that the entire paragraph, above, appears to be lifted virtually verbatim from Berglund's article (compare the two paragraphs, below).

Hmmmm. Pelmeur/Leventhall fail to acknowledge Berglund as their (apparent) source, nor do they put quotation marks around their text. A double infraction. (When I was a university professor, I gave students a failing grade for copying someone else's material without credit; indeed I had a colleague who was de-tenured and fired for publishing other people's text without credit.)

At a minimum, Leventhall appears to be careless. He also appears to be indecisive. Mostly, however, given the growing body of research on low frequency noise from industrial wind turbines (see GP van den Berg's scholarly articles, along with Dr. Q. Soysal's noise measurements at the Meyersdale, PA, USA, windplant, and Dr. DMJP Manley's research), Leventhall seems to be a man representing, above all, the agenda of the wind energy companies (like Noble Environmental, LLC) that employ his services.

.....

I have always said, and am now backed up by recent work from others, that there is no problem of infrasound from wind turbines.

— Geoffrey Leventhall, *Malone (New York, USA) Telegram*, 9-12-05, p. 4

Dr Geoff Leventhall, a noise vibration and acoustics expert from the UK who looked into infrasound at the request of Genesis Power, says "I can state quite categorically that there is no significant Infrasound from current designs of wind turbines".

— Geoffrey Leventhall, *Hawke's Bay Today (New Zealand)*, 2-18-06

Infrasound exposure is ubiquitous in modern life. It is generated by natural sources such as earthquakes and wind. It is common in urban environments, and as an emission from many artificial sources: automobiles, ... aircraft, industrial machinery, artillery and mining explosions, air movement machinery including wind turbines, compressors, and ventilation or air-conditioning

units.... The effects of infrasound or low frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficiency of many structures (dwellings, walls, and hearing protection) in attenuating low frequency noise compared with other noise.

- Geoffrey Leventhall, "A Review of Published Research on Low Frequency Noise and Its Effects," Report for DEFRA (United Kingdom) by Dr. Geoff Leventhall, Assisted by Dr. Peter Pelemear and Dr. Stephen Benton, **May 2003**, p. 54.

Low-frequency noise is common as background noise in urban environments, and as an emission from many artificial sources: road vehicles, aircraft, industrial machinery, artillery and mining explosions, and air movement machinery including wind turbines, compressors, and ventilation or air-conditioning units. The effects of low-frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficacy of many structures (dwellings, walls, and hearing protection) in attenuating low-frequency noise compared with other noise.

- B. Berglund, P. Hassmen, and RF Job, "Sources and Effects of Low-Frequency Noise," Journal of the Acoustical Society of America, vol. 99, no. 5 (**May 1996**):2985-3002, Abstract.

Letters to the editor

Not 'employee of Noble'

To the editor:

I am accustomed to having my views misrepresented by both sides of the wind farm debate, but in her letter published on August 30th, Kaye Johnson is going a bit too far. I believe that she has impugned my ethics, morality and scientific integrity. Although it would probably be futile to ask her for an apology, I expect you, as a party to this, to publish some facts.

I am not "an employee of Noble," a term which implies dependence on them for my income. I am an independent noise and vibration consultant and Noble is one of my many clients, contributing a very small part of my turnover.

I have never "provided the scientific community with hard evidence about the severity of the noise problem around industrial wind turbines." That is one of the many misrepresentations by objector groups. I am known internationally for my work on infrasound and low frequency noise, which is the area for which Noble retained me, as it is in these areas that I have made statements about wind turbine noise. I have been consistent in my views and am not now "singing a different song."

I have always said, and am now backed up by recent work from others, that there is no problem of infrasound from wind turbines.

Low frequency noise arises from the mechanical systems in wind turbines and from particular inflow air conditions. Mechanical noise is not a problem in modern wind turbines. Turbulent air inflow may increase levels of low frequency noise due to the interaction of the blades with the turbu-

lence. This is normally an occasional occurrence for a turbine, if at all.

The regular swish - swish from wind turbines is not low frequency noise, but a change in level of a high frequency. This is an important point as, over the years, infrasound and low frequency noise have attracted a lot of negative baggage, which has been applied, incorrectly and without justification, to wind turbines. My advice to objector groups in this connection has been that, by squandering their energies on infrasound and low frequency noise, they are losing credibility and not giving sufficient attention to other factors, such as optimum siting of the turbines.

I am organising an International Conference on Wind Turbine Noise to be held in Berlin, Germany 17/18 October 2005 - see www.windturbinenoise2005.org - where it is hoped that delegates from all sides of the debate will be present.

Dr. Geoff Leventhal
Ashted, Surrey, UK

"And the beat goes on . . .and on and on"

Hawke's Bay Today (New Zealand), February 18, 2006

KATHY WEBB

They call it the train that never arrives. It's a low, rumbling sound that goes on and on ... and on.

Sometimes, in a stiff easterly, the rumbling develops into a roar, like a stormy ocean.

But worst of all is the beat. An insidious, low-frequency vibration that's more a sensation than a noise. It defeats double-glazing and ear plugs, coming up through the ground, or through the floors of houses, and manifesting itself as a ripple up the spine, a thump on the chest or a throbbing in the ears. Those who feel it say it's particularly bad at night. It wakes them up or stops them getting to sleep.

Wendy Brock says staff from Meridian Energy promised her the wind turbines at Te Apiti, 2.5km [1.6 miles] from her Ashhurst home in southern Hawke's Bay, would be no noisier than waves swishing on a seashore.

"They stood in my lounge and told me that."

But during a strong easterly, the noise emitted by the triffid-like structures waving their arms along the skyline and down the slopes behind the Brock family's lifestyle block is more like a thundering, stormy ocean. Sometimes it goes on for days. And when the air is still, there's the beat - rhythmic and relentless, "like the boom box in a teenager's car".

"It comes up through the floor of our house. You can't stop it."

Mrs Brock says she can feel it rippling along her spine when she's lying in bed at night. Blocking her ears makes no difference.

"It irritates you, night after night. Imagine you've done your day's work, then you go to bed, and there's this bass beat coming up through the floor and you can't go to sleep. You can't even put headphones on and get away from it.

"My older son sometimes gets woken up by the noise. He gets up and prowls around the house."

She tells of other Ashhurst residents who "feel" the sound hitting their chests in the Ashhurst Domain 3km [1.9 miles] from the turbines. She says one woman is so distressed by the sensation she has put her home on the market.

Not everyone in the village hears the infrasound - Mrs Brock reels off the names of residents wondering what the fuss is all about - but says those who do feel the sound are distressed by it and have nowhere to turn for redress.

There's little point complaining to the Tararua District Council because all it does is record each complaint and forward it to Meridian, and nothing ever happens.

"What are they (the council) going to do to Meridian - fine them, or shut down the

turbines?" asks Mrs Brock.

Meridian is dismissive of complaints about noise from Te Apiti.

"Infrasound is just not an issue with modern turbines," insists spokesman Alan Seay.

"We take it very seriously. We have looked into it seriously, but the advice we are getting from eminently qualified people is that it is just not an issue."

Many people claiming to be putting forward scientific argument about noise from turbines "are not qualified in this area of expertise. I have a problem with some of their statements", Mr Seay said.

He asked Hawke's Bay Today for the names of those complaining about noise from Te Apiti.

Asked why he wanted the names, he replied: "There is a group of people there. They are opposed to wind farms per se".

Asked why he thought they were opposed, Mr Seay said "I don't want to speculate. They just are. Possibly for the visual impact."

Meridian had complied with all legal requirements for sound emissions from Te Apiti, and "the people of Ashhurst are very happy to have those turbines there. They have become an icon," Mr Seay said.

Meridian is currently appealing noise restrictions placed on its proposed 70-turbine wind farm at Makara, near Wellington, where some houses will be about 1km [0.6 miles] away, and downwind of, the turbines.

John Napier lives on the Woodville side of the Te Apiti turbines, about 2km [1.24 miles] from the nearest one.

When they first began operating, he couldn't believe the roaring noise they made.

"We can hear it in our bedroom at night."

One night, about 2am, he got out of bed to check whether the bedroom windows were vibrating, and about five times since, he has been woken up and thought "they're making a racket tonight".

He doesn't hear the infrasound beat so much. It's mainly "a roar like a train going through a tunnel or over a bridge, but it never stops".

He complained to Meridian about the noise, and the company put a noise meter on his property for a couple of weeks, but wouldn't tell him the results.

"Wind farm companies say noise from turbines is not an issue, but it is an issue all right. I would be very concerned if I lived in Karori (near Makara, in Wellington)," Mr Napier said.

Harvey Jones, who lives in a valley 3km [1.9 miles] from Te Apiti, says there is an easterly wind blowing across the wind farm about 10 percent of the time. The wind

goes across the top of the hill, but the noise from the turbines rolls down the valley. It sounds like a train constantly passing by, and the stronger the wind, the louder the noise. When there's a westerly blowing, he can even hear the turbines in Woodville, 6-7km [3.7 to 4.3 miles] away.

"Once you get tuned in to it you can easily pick it up," he says.

Mr Jones says the amount of noise generated by the Te Aitū turbines was unexpected, and landowners prepared to put turbines on their land at Te Pohue should think very carefully about the possibility of a repeat scenario.

He predicts disaster for the residents of Makara and Karori.

"They're going to get hammered, but they don't realise."

Steve Griffin, of Te Pohue, is secretary of the Outstanding Natural Landscape Protection Society, formed to oppose two windfarms proposed for his area on the Napier-Taupo road.

Lines company Unison has resource consent to put up about 50 turbines, and Hawke's Bay Windfarms plans to erect 75 turbines nearby.

The landscape protection society is appealing all the consents in the Environment Court.

Mr Griffin, who is "sick to death of wind farms", says the prospect of 128 giant industrial turbines visually disrupting pristine skyline and covering more than 16km [10 miles] of prominent mountain range near Te Pohue is bad enough. But he and other residents are worried sick about the noise potential - both normal-range and infrasound - from the turbines. Each turbine will have an 80m tower and three 45m blades. They will be 125m high and 90m wide, each taking up the equivalent of 1.5 rugby fields.

They will encircle Te Pohue village and its school, in a valley downwind of the turbines in prevailing winds - and nobody in authority seems to care, he says.

The Government has thrown the doors wide open to wind farm developers, in a bid to meet its Kyoto commitments; there are no national guidelines specific to wind turbines. That stance is unbalanced and unfair, Mr Griffin says.

"Our view is that while wind farms are part of our energy solution, sites must be selected in a socially responsible manner.

"They should not be placed within 5km [3 miles] of schools, hospitals, rest homes, or the private homes of those not involved with a wind farm development."

They should also be kept out of coastal, and recreation areas, and those with high scenic value, he says.

The landscape protection society wants the Government to establish national guidelines for wind farms, and review noise-testing standards to include measurement of low-frequency sound.

Low-frequency sound - sometimes called infrasound - is controversial.

Dr Geoff Leventhall, a noise vibration and acoustics expert from the UK who looked into infrasound at the request of Genesis Power, says "I can state quite categorically that there is no significant infrasound from current designs of wind turbines".

He says "the ear is the most sensitive receptor in the body, so if you cannot hear it you cannot feel it". Engineer Ken Mosley, of Silverstream, has an entirely different view.

The foundations of modern turbines create vibrations in the ground when they are moving, and also sometimes when they are not moving, Dr Mosley says.

"This vibration is transmitted seismically through the ground in a similar manner to earthquake shocks and roughly at similar frequencies.

"Generally, the vibrations cannot be heard until they cause the structure of a house to vibrate in sympathy, and then only inside the house. The effects inside appear as noise and vibrations in certain parts of a room. Outside these areas, little is heard or felt.

"However, the low frequency components of the noise and vibration can cause very unpleasant effects which eventually cause the health of people to deteriorate to an extent where living in the property can become impossible."

Dr Mosley says that wherever wind farms are built close to houses, people complain about noise and vibration.

He quotes a scientist in South West Wales, David Manley, who has been researching noise and vibration phenomena associated with turbines since 1994.

An acoustician and engineer, Dr Manley writes "it is found that people living within 8.2km [5 miles] of a wind farm cluster can be affected and if they are sensitive to low frequencies they may be disturbed".

Two GPs in the UK have researched the health effects of noise and vibrations from turbines. Amanda Harry documented complaints of headaches, migraines, nausea, dizziness, palpitations, sleep disturbance, stress, anxiety and depression. People suffered flow-on effects of being irritable, unable to concentrate during the day, losing the ability to cope.

Bridget Osborne, of Moel Maelogan, a village in North Wales, where three turbines were erected in 2002, is reported as saying "there is a public perception that wind power is 'green' and has no detrimental effect on the environment, but these turbines make low-frequency noises that can be as damaging as high-frequency noises.

"When wind farm developers do surveys to assess the suitability of a site they measure the audible range of noise but never the infrasound measurement - the low-frequency noise that causes vibrations that you can feel through your feet and chest.

"This frequency resonates with the human body, their effect being dependent on body shape. There are those on whom there is virtually no effect, but others for whom it is incredibly disturbing."

Dr Mosley says wind-power generators in New Zealand are aware of such literature on turbine noise and infrasound from all around the world.

"Are they therefore just ignoring what is happening in the rest of the world in the hope that once turbines are up and running, people will quietly endure, or when the noise/vibration situation really starts to damage their health, the community will cut their losses, leave their homes and quietly fade away? Of course, wherever they end up, they must still pay their electricity bills, which is rather like paying the landlord who has evicted you."

The New Zealand Wind Energy Association, which did not return calls from Hawke's Bay Today, acknowledges that turbines produce infrasound, but insists it is so minimal from modern turbines that human beings cannot perceive it. Its website says "there is no evidence to indicate that low frequency sound or infrasound from current models of wind turbine should cause concern."

Infrasound was more of a problem with older turbines, which had their blades downwind of the turbine tower, the association says.

"That caused a low frequency thump each time a blade passed behind the tower."

In contrast, modern turbines "have their blades upwind of the tower, thus reducing the level of this type of noise to below the threshold of human perception, thereby minimising any possible effect on human health or wellbeing".

The association has published excerpts of a report by Dr Leventhall, who suggests that infrasound is a concept that could be classified as pop-science, seized upon by emotionally-overwrought wind farm opponents.

"When a group of residents decides to object to a development, they often support each other with strong emotions, which can sometimes lead them astray. The emphasis on low-frequency noise is an example of this. Over the past 30 years there has been a great deal of confusion and misinformation about low frequency noise, mainly in the popular media. Much of it can best be described as "hot air" but complainants' uncritical acceptance of what they read in unreliable sources has two unfortunate effects:

- It detracts from those people who have genuine low-frequency noise problems, often from industrial exhaust fans, compressors and similar.
- It undermines the credibility of the complainants, who may be harming their own cause in their apparent 'grasping at straws' approach."

Dr Leventhall goes on to say "the rational study of low frequency noise, its effects and criteria for control, has been bedeviled by exaggerations, half-truths and misrepresentations, much of it fomented by media stories over the last 35 years. The result in the UK, and it is probably similar in other countries, is that an incorrect concept - 'low frequency noise is a hazard' - has taken root in the national psyche, where it lies dormant waiting for a trigger to arouse it. The current trigger is wind turbines."

Or Leventhall says:

- High levels of low-frequency noise are needed before people can perceive it, and the levels must increase as frequency reduces.
- The ear is the most sensitive receptor in the body, so if you cannot hear it you cannot feel it.
- When there are problems with predominantly low-frequency noise, that is because assessment methods do not cater for it. That leads to the noises being dismissed as not being a nuisance, which in turn leaves unhappy complainants in a distressed state.

Up on the Napier-Taupo road, the printer in Steve Griffin's office is working overtime in preparation for an Environment Court battle. It might be a David and Goliath confrontation, but there's too much at stake to sit back and take it quietly, he says.

Note: "Hawkes Bay Today is the regional daily newspaper for Hawkes Bay. Our circulation area ranges from Mahia in north to Dannevirke in the South and to the central ranges in the west. We are also the youngest newspaper in New Zealand, launched on May 3, 1999."

A Review of Published Research on Low Frequency Noise and its Effects

**Report for Defra by Dr Geoff Leventhall
Assisted by Dr Peter Palmear and Dr Stephen Benton**

May 2003

many parameters measured was an insignificant (< 1.5 mm Hg) increase in the minimal arterial blood pressure. However, Borredon also reported that several of his subjects felt drowsy after the infrasound exposure.

- 13.2 Effects on humans.** Infrasound exposure is ubiquitous in modern life. It is generated by natural sources such as earthquakes and wind. It is common in urban environments, and as an emission from many artificial sources: automobiles, rail traffic, aircraft, industrial machinery, artillery and mining explosions, air movement machinery including wind turbines, compressors, and ventilation or air-conditioning units, household appliances such as washing machines, and some therapeutic devices. The effects of infrasound or low frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficiency of many structures (dwellings, walls, and hearing protection) in attenuating low-frequency noise compared with other noise.

In humans the effects studied have been on the cardiovascular and nervous systems, eye structure, hearing and vestibular function, and the endocrine system. Special central nervous system (CNS) effects studied included annoyance, sleep and wakefulness, perception, evoked potentials, electroencephalographic changes, and cognition. Reduction in wakefulness during periods of infrasonic exposure above the hearing threshold has been identified through changes in EEG, blood pressure, respiration, hormonal production, performance and heart activity. Infrasound has been observed to affect the pattern of sleep minutely. Exposure to 6 and 16 Hz levels at 10 dB above the auditory threshold have been associated with a reduction in wakefulness (Landström and Byström, 1984). It has also been possible to confirm that the reduction on wakefulness is based on hearing perception since deaf subjects have an absence of weariness (Landström, 1987).

In moderate infrasonic exposures, the physiological effects observed in experimental studies often seem to reflect a general slowdown of the physiological and psychological state. The reduction in wakefulness and the correlated physiological responses are not isolated phenomena and the physiological changes are considered to be secondary reactions to a primary effect on the CNS. The effects of moderate infrasound exposure are thought to arise from a correlation between hearing perception and a following stimulation of the CNS. The participation of the reticular activating system (RAS) and the hypothalamus is thought to be of great importance. Taking this into account, changes in the physiological reactions are not just a question of whether the sound waves are above the hearing threshold. Furthermore reactions within the CNS, including RAS, hypothalamus, limbic system, and cortical regions are probably highly influenced by the quality of the sound. Some frequencies and characters of the noise are probably more effective than others for producing weariness.

A high degree of caution is necessary before ascribing the origin of physiological changes in working situations to infrasonic exposure because of their association. When analysing the factors promoting fatigue e.g. driving, many aspects have to be considered. The environment is usually a combination of many factors such as seat comfort, visibility, instrumentation,

Sources and effects of low-frequency noise.

Berglund B, Hassmen P, Job RF.

Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden.
bb@psychology.su.se

The sources of human exposure to low-frequency noise and its effects are reviewed. Low-frequency noise is common as background noise in urban environments, and as an emission from many artificial sources: road vehicles, aircraft, industrial machinery, artillery and mining explosions, and air movement machinery including wind turbines, compressors, and ventilation or air-conditioning units. The effects of low-frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficacy of many structures (dwellings, walls, and hearing protection) in attenuating low-frequency noise compared with other noise. Intense low-frequency noise appears to produce clear symptoms including respiratory impairment and aural pain. Although the effects of lower intensities of low-frequency noise are difficult to establish for methodological reasons, evidence suggests that a number of adverse effects of noise in general arise from exposure to low-frequency noise: Loudness judgments and annoyance reactions are sometimes reported to be greater for low-frequency noise than other noises for equal sound-pressure level; annoyance is exacerbated by rattle or vibration induced by low-frequency noise; speech intelligibility may be reduced more by low-frequency noise than other noises except those in the frequency range of speech itself, because of the upward spread of masking. On the other hand, it is also possible that low-frequency noise provides some protection against the effects of simultaneous higher frequency noise on hearing. Research needs and policy decisions, based on what is currently known, are considered.

Letters to the editor

Not 'employee of Noble'

To the editor:

I am accustomed to having my views misrepresented by both sides of the wind farm debate, but in her letter published on August 30th, Kays Johnson is going a bit too far. I believe that she has impugned my ethics, morality and scientific integrity. Although it would probably be futile to ask her for an apology, I expect you, as a party to this, to publish some facts.

I am not "an employee of Noble," a term which implies dependence on them for my income. I am an independent noise and vibration consultant and Noble is one of my many clients, contributing a very small part of my turnover.

I have never "provided the scientific community with hard evidence about the severity of the noise problem around industrial wind turbines." That is one of the many misrepresentations by objector groups. I am known internationally for my work on infrasound and low frequency noise, which is the area for which Noble retained me, as it is in these areas that I have made statements about wind turbine noise. I have been consistent in my views and am not now "singing a different song."

I have always said, and am now backed up by recent work from others, that there is no problem of infrasound from wind turbines.

Low frequency noise arises from the mechanical systems in wind turbines and from particular inflow air conditions. Mechanical noise is not a problem in modern wind turbines. Turbulent air inflow may increase levels of low frequency noise due to the interaction of the blades with the turbu-

lence. This is normally an occasional occurrence for a turbine, if at all.

The regular swish - swish from wind turbines is not low frequency noise, but a change in level of a high frequency. This is an important point as, over the years, infrasound and low frequency noise have attracted a lot of negative baggage, which has been applied, incorrectly and without justification, to wind turbines. My advice to objector groups in this connection has been that, by squandering their energies on infrasound and low frequency noise, they are losing credibility and not giving sufficient attention to other factors, such as optimum siting of the turbines.

I am organising an International Conference on Wind Turbine Noise to be held in Berlin, Germany 17/18 October 2005 - see www.windturbine-noise2005.org - where it is hoped that delegates from all sides of the debate will be present.

"And the beat goes on . . . and on and on"

Hawke's Bay Today (New Zealand), February 18, 2006

KATHY WEBB

They call it the train that never arrives. It's a low, rumbling sound that goes on and on ... and on.

Sometimes, in a stiff easterly, the rumbling develops into a roar, like a stormy ocean.

But worst of all is the beat. An insidious, low-frequency vibration that's more a sensation than a noise. It defeats double-glazing and ear plugs, coming up through the ground, or through the floors of houses, and manifesting itself as a ripple up the spine, a thump on the chest or a throbbing in the ears. Those who feel it say it's particularly bad at night. It wakes them up or stops them getting to sleep.

Wendy Brock says staff from Meridian Energy promised her the wind turbines at Te Apiti, 2.5km [1.6 miles] from her Ashhurst home in southern Hawke's Bay, would be no noisier than waves swishing on a seashore.

"They stood in my lounge and told me that."

But during a strong easterly, the noise emitted by the tuffid-like structures waving their arms along the skyline and down the slopes behind the Brock family's lifestyle block is more like a thundering, stormy ocean. Sometimes it goes on for days. And when the air is still, there's the beat - rhythmic and relentless, "like the boom box in a teenager's car".

"It comes up through the floor of our house. You can't stop it."

Mrs Brock says she can feel it rippling along her spine when she's lying in bed at night. Blocking her ears makes no difference.

"It irritates you, night after night. Imagine you've done your day's work, then you go to bed, and there's this bass beat coming up through the floor and you can't go to sleep. You can't even put headphones on and get away from it.

"My older son sometimes gets woken up by the noise. He gets up and prowls around the house."

She tells of other Ashhurst residents who "feel" the sound hitting their chests in the Ashhurst Domain 3km [1.9 miles] from the turbines. She says one woman is so distressed by the sensation she has put her home on the market.

Not everyone in the village hears the infrasound - Mrs Brock reels off the names of residents wondering what the fuss is all about - but says those who do feel the sound are distressed by it and have nowhere to turn for redress.

There's little point complaining to the Tararua District Council because all it does is record each complaint and forward it to Meridian, and nothing ever happens.

"What are they (the council) going to do to Meridian - fine them, or shut down the

turbines?" asks Mrs Brock.

Meridian is dismissive of complaints about noise from Te Apitī.

"Infrasound is just not an issue with modern turbines," insists spokesman Alan Seay.

"We take it very seriously. We have looked into it seriously, but the advice we are getting from eminently qualified people is that it is just not an issue."

Many people claiming to be putting forward scientific argument about noise from turbines "are not qualified in this area of expertise. I have a problem with some of their statements", Mr Seay said.

He asked Hawke's Bay Today for the names of those complaining about noise from Te Apitī.

Asked why he wanted the names, he replied: "There is a group of people there. They are opposed to wind farms per se".

Asked why he thought they were opposed, Mr Seay said "[I] don't want to speculate. They just are. Possibly for the visual impact."

Meridian had complied with all legal requirements for sound emissions from Te Apitī, and "the people of Ashhurst are very happy to have those turbines there. They have become an icon," Mr Seay said.

Meridian is currently appealing noise restrictions placed on its proposed 70-turbine wind farm at Makara, near Wellington, where some houses will be about 1km [0.6 miles] away, and downwind of, the turbines.

John Napier lives on the Woodville side of the Te Apitī turbines, about 2km [1.24 miles] from the nearest one.

When they first began operating, he couldn't believe the roaring noise they made.

"We can hear it in our bedroom at night."

One night, about 2am, he got out of bed to check whether the bedroom windows were vibrating, and about five times since, he has been woken up and thought "they're making a racket tonight".

He doesn't hear the infrasound beat so much. It's mainly "a roar like a train going through a tunnel or over a bridge, but it never stops".

He complained to Meridian about the noise, and the company put a noise meter on his property for a couple of weeks, but wouldn't tell him the results.

"Wind farm companies say noise from turbines is not an issue, but it is an issue all right. I would be very concerned if I lived in Karori (near Makara, in Wellington)," Mr Napier said.

Harvey Jones, who lives in a valley 3km [1.9 miles] from Te Apitī, says there is an easterly wind blowing across the wind farm about 10 percent of the time. The wind

goes across the top of the hill, but the noise from the turbines rolls down the valley. It sounds like a train constantly passing by, and the stronger the wind, the louder the noise. When there's a westerly blowing, he can even hear the turbines in Woodville, 6-7km [3.7 to 4.3 miles] away.

"Once you get tuned in to it you can easily pick it up," he says.

Mr Jones says the amount of noise generated by the Te Apiti turbines was unexpected, and landowners prepared to put turbines on their land at Te Pohue should think very carefully about the possibility of a repeat scenario.

He predicts disaster for the residents of Makara and Karori.

"They're going to get hammered, but they don't realise."

Steve Griffin, of Te Pohue, is secretary of the Outstanding Natural Landscape Protection Society, formed to oppose two windfarms proposed for his area on the Napier-Taupo road.

Lines company Unison has resource consent to put up about 50 turbines, and Hawke's Bay Windfarms plans to erect 75 turbines nearby.

The landscape protection society is appealing all the consents in the Environment Court.

Mr Griffin, who is "sick to death of wind farms", says the prospect of 128 giant industrial turbines visually disrupting pristine skyline and covering more than 16km [10 miles] of prominent mountain range near Te Pohue is bad enough. But he and other residents are worried sick about the noise potential - both normal-range and infrasound - from the turbines. Each turbine will have an 80m tower and three 45m blades. They will be 125m high and 90m wide, each taking up the equivalent of 1.5 rugby fields.

They will encircle Te Pohue village and its school, in a valley downwind of the turbines in prevailing winds - and nobody in authority seems to care, he says.

The Government has thrown the doors wide open to wind farm developers, in a bid to meet its Kyoto commitments; there are no national guidelines specific to wind turbines. That stance is unbalanced and unfair, Mr Griffin says.

"Our view is that while wind farms are part of our energy solution, sites must be selected in a socially responsible manner.

"They should not be placed within 5km [3 miles] of schools, hospitals, rest homes, or the private homes of those not involved with a wind farm development."

They should also be kept out of coastal, and recreation areas, and those with high scenic value, he says.

The landscape protection society wants the Government to establish national guidelines for wind farms, and review noise-testing standards to include measurement of low-frequency sound.

Low-frequency sound – sometimes called infrasound – is controversial.

Dr Geoff Leventhall, a noise vibration and acoustics expert from the UK who looked into infrasound at the request of Genesis Power, says "I can state quite categorically that there is no significant infrasound from current designs of wind turbines".

He says "the ear is the most sensitive receptor in the body, so if you cannot hear it you cannot feel it". Engineer Ken Mosley, of Silverstream, has an entirely different view.

The foundations of modern turbines create vibrations in the ground when they are moving, and also sometimes when they are not moving, Dr Mosley says.

"This vibration is transmitted seismically through the ground in a similar manner to earthquake shocks and roughly at similar frequencies.

"Generally, the vibrations cannot be heard until they cause the structure of a house to vibrate in sympathy, and then only inside the house. The effects inside appear as noise and vibrations in certain parts of a room. Outside these areas, little is heard or felt.

"However, the low frequency components of the noise and vibration can cause very unpleasant effects which eventually cause the health of people to deteriorate to an extent where living in the property can become impossible."

Dr Mosley says that wherever wind farms are built close to houses, people complain about noise and vibration.

He quotes a scientist in South West Wales, David Manley, who has been researching noise and vibration phenomena associated with turbines since 1994.

An acoustician and engineer, Dr Manley writes "it is found that people living within 8.2km [5 miles] of a wind farm cluster can be affected and if they are sensitive to low frequencies they may be disturbed".

Two GPs in the UK have researched the health effects of noise and vibrations from turbines. Amanda Harry documented complaints of headaches, migraines, nausea, dizziness, palpitations, sleep disturbance, stress, anxiety and depression. People suffered flow-on effects of being irritable, unable to concentrate during the day, losing the ability to cope.

Bridget Osborne, of Moel Maelogan, a village in North Wales, where three turbines were erected in 2002, is reported as saying "there is a public perception that wind power is 'green' and has no detrimental effect on the environment, but these turbines make low-frequency noises that can be as damaging as high-frequency noises.

"When wind farm developers do surveys to assess the suitability of a site they measure the audible range of noise but never the infrasound measurement – the low-frequency noise that causes vibrations that you can feel through your feet and chest.

"This frequency resonates with the human body, their effect being dependent on body shape. There are those on whom there is virtually no effect, but others for whom it is incredibly disturbing."

Dr Mosley says wind-power generators in New Zealand are aware of such literature on turbine noise and infrasound from all around the world.

"Are they therefore just ignoring what is happening in the rest of the world in the hope that once turbines are up and running, people will quietly endure, or when the noise/vibration situation really starts to damage their health, the community will cut their losses, leave their homes and quietly fade away? Of course, wherever they end up, they must still pay their electricity bills, which is rather like paying the landlord who has evicted you."

The New Zealand Wind Energy Association, which did not return calls from Hawke's Bay Today, acknowledges that turbines produce infrasound, but insists it is so minimal from modern turbines that human beings cannot perceive it. Its website says "there is no evidence to indicate that low frequency sound or infrasound from current models of wind turbine should cause concern."

Infrasound was more of a problem with older turbines, which had their blades downwind of the turbine tower, the association says.

"That caused a low frequency thump each time a blade passed behind the tower."

In contrast, modern turbines "have their blades upwind of the tower, thus reducing the level of this type of noise to below the threshold of human perception, thereby minimising any possible effect on human health or wellbeing".

The association has published excerpts of a report by Dr Leventhall, who suggests that infrasound is a concept that could be classified as pop-science, seized upon by emotionally-overwrought wind farm opponents.

"When a group of residents decides to object to a development, they often support each other with strong emotions, which can sometimes lead them astray. The emphasis on low-frequency noise is an example of this. Over the past 30 years there has been a great deal of confusion and misinformation about low frequency noise, mainly in the popular media. Much of it can best be described as "hot air" but complainants' uncritical acceptance of what they read in unreliable sources has two unfortunate effects:

- It detracts from those people who have genuine low-frequency noise problems, often from industrial exhaust fans, compressors and similar.
- It undermines the credibility of the complainants, who may be harming their own cause in their apparent 'grasping at straws' approach."

Dr Leventhall goes on to say "the rational study of low frequency noise, its effects and criteria for control, has been bedeviled by exaggerations, half-truths and misrepresentations, much of it fomented by media stories over the last 35 years. The result in the UK, and it is probably similar in other countries, is that an incorrect concept - 'low frequency noise is a hazard' - has taken root in the national psyche, where it lies dormant waiting for a trigger to arouse it. The current trigger is wind turbines."

Dr Leventhall says:

- High levels of low-frequency noise are needed before people can perceive it, and the levels must increase as frequency reduces.
- The ear is the most sensitive receptor in the body, so if you cannot hear it you cannot feel it.
- When there are problems with predominantly low-frequency noise, that is because assessment methods do not cater for it. That leads to the noises being dismissed as not being a nuisance, which in turn leaves unhappy complainants in a distressed state.

Up on the Napier-Taupo road, the printer in Steve Griffin's office is working overtime in preparation for an Environment Court battle. It might be a David and Goliath confrontation, but there's too much at stake to sit back and take it quietly, he says.

Note: "Hawkes Bay Today is the regional daily newspaper for Hawkes Bay. Our circulation area ranges from Mahia in north to Dannevirke in the South and to the central ranges in the west. We are also the youngest newspaper in New Zealand, launched on May 3, 1999."

A Review of Published Research on Low Frequency Noise and its Effects

**Report for Defra by Dr Geoff Leventhall
Assisted by Dr Peter Palmear and Dr Stephen Benton**

May 2003

many parameters measured was an insignificant (< 1.5 mm Hg) increase in the minimal arterial blood pressure. However, Borredon also reported that several of his subjects felt drowsy after the infrasound exposure.

- 13.2 Effects on humans.** Infrasound exposure is ubiquitous in modern life. It is generated by natural sources such as earthquakes and wind. It is common in urban environments, and as an emission from many artificial sources: automobiles, rail traffic, aircraft, industrial machinery, artillery and mining explosions, air movement machinery including wind turbines, compressors, and ventilation or air-conditioning units, household appliances such as washing machines, and some therapeutic devices. The effects of infrasound or low frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficiency of many structures (dwellings, walls, and hearing protection) in attenuating low-frequency noise compared with other noise.

In humans the effects studied have been on the cardiovascular and nervous systems, eye structure, hearing and vestibular function, and the endocrine system. Special central nervous system (CNS) effects studied included annoyance, sleep and wakefulness, perception, evoked potentials, electroencephalographic changes, and cognition. Reduction in wakefulness during periods of infrasonic exposure above the hearing threshold has been identified through changes in EEG, blood pressure, respiration, hormonal production, performance and heart activity. Infrasound has been observed to affect the pattern of sleep minutely. Exposure to 6 and 16 Hz levels at 10 dB above the auditory threshold have been associated with a reduction in wakefulness (Landström and Byström, 1984). It has also been possible to confirm that the reduction on wakefulness is based on hearing perception since deaf subjects have an absence of weariness (Landström, 1987).

In moderate infrasonic exposures, the physiological effects observed in experimental studies often seem to reflect a general slowdown of the physiological and psychological state. The reduction in wakefulness and the correlated physiological responses are not isolated phenomena and the physiological changes are considered to be secondary reactions to a primary effect on the CNS. The effects of moderate infrasound exposure are thought to arise from a correlation between hearing perception and a following stimulation of the CNS. The participation of the reticular activating system (RAS) and the hypothalamus is thought to be of great importance. Taking this into account, changes in the physiological reactions are not just a question of whether the sound waves are above the hearing threshold. Furthermore reactions within the CNS, including RAS, hypothalamus, limbic system, and cortical regions are probably highly influenced by the quality of the sound. Some frequencies and characters of the noise are probably more effective than others for producing weariness.

A high degree of caution is necessary before ascribing the origin of physiological changes in working situations to infrasonic exposure because of their association. When analysing the factors promoting fatigue e.g. driving, many aspects have to be considered. The environment is usually a combination of many factors such as seat comfort, visibility, instrumentation,

The sources of human exposure to low-frequency noise and its effects are reviewed. Low-frequency noise is common as background noise in urban environments, and as an emission from many artificial sources: road vehicles, aircraft, industrial machinery, artillery and mining explosions, and air movement machinery including wind turbines, compressors, and ventilation or air-conditioning units. The effects of low-frequency noise are of particular concern because of its pervasiveness due to numerous sources, efficient propagation, and reduced efficacy of many structures (dwellings, walls, and hearing protection) in attenuating low-frequency noise compared with other noise. Intense low-frequency noise appears to produce clear symptoms including respiratory impairment and aural pain. Although the effects of lower intensities of low-frequency noise are difficult to establish for methodological reasons, evidence suggests that a number of adverse effects of noise in general arise from exposure to low-frequency noise: Loudness judgments and annoyance reactions are sometimes reported to be greater for low-frequency noise than other noises for equal sound-pressure level; annoyance is exacerbated by rattle or vibration induced by low-frequency noise; speech intelligibility may be reduced more by low-frequency noise than other noises except those in the frequency range of speech itself, because of the upward spread of masking. On the other hand, it is also possible that low-frequency noise provides some protection against the effects of simultaneous higher frequency noise on hearing. Research needs and policy decisions, based on what is currently known, are considered.

Microseismic and Infrasound Monitoring of Low Frequency Noise and Vibrations from Windfarms

Recommendations on the Siting of Windfarms in the Vicinity of Eskdalemuir, Scotland

Abstract

In order to meet, and in fact exceed, Kyoto targets, the UK government has set a challenging target of reducing the UK's carbon dioxide emissions by 60% by 2050. The development of renewable energy, especially wind power, will be an important contributor to the success of that policy.

Some 40% (in excess of 1 Gigawatt), of this wind generation capacity, was planned for the southern uplands of Scotland. However, the United Kingdom seismic monitoring site which constitutes our component of the Comprehensive Test Ban Treaty compliance for nuclear testing is situated at Eskdalemuir near Langholm in the Scottish Borders. The Ministry of Defence therefore placed a precautionary blanket objection to any wind farm developments within 80 km of Eskdalemuir in case this compromised UK capability to detect distant nuclear test and breached our agreement under the CTBT. This effectively removed at least 40% of the UK renewable wind resource identified by the DTI.

Because of our previous, unique experience in monitoring seismic vibrations from wind turbines in the UK, the Applied and Environmental Geophysics Group of the School of Physical and Geographical Sciences at Keele University, were asked by the MOD, the DTI and the British Wind Energy Association to investigate whether there was a solution to this impasse. By carrying out a detailed programme of seismic and infrasound measurements in the vicinity of several wind farms in Scotland we have been able to identify the characteristic frequencies and mode of propagation of seismic vibrations from wind turbines and develop a model for the integrated seismic vibration at the Eskdalemuir site which will be created by any distribution of wind farms. By carefully considering the present ambient background experienced at the monitoring site it has been possible to set a noise budget which is permissible at Eskdalemuir without compromising its detection capabilities, and we have demonstrated that at least 1.6 GW of planned capacity can be installed and have developed software tools which allow the MOD and planners to assess what further capacity can be developed against criteria established by this study.

Introduction

The Eskdalemuir Seismic Array (EKA)

Eskdalemuir in the Scottish Borders is the location of a monitoring facility operated by the British Geological Survey where seismological, magnetic and other environmental parameters are monitored because the site is located in a very quiet magnetic and seismic environment. Measurements include horizontal and vertical magnetic field components and declination, total field intensity, and absolute values of the geomagnetic field. Three-component seismological measurements are made at the sites. An environmental monitoring facility operates at Eskdalemuir, monitoring soil and air temperature, wind speed and direction; UV and nuclear radiation; sunshine; concentrations of ozone, SO₂ and NO_x gases; rainfall; humidity and surface wetness.

In addition the UK seismological array (EKA) operated by AWE Blacknest is also sited at Eskdalemuir. The facility at Eskdalemuir is part of the auxiliary seismic network of the International Monitoring System (IMS) being set up to help verify compliance with the Comprehensive Test Ban Treaty (CTBT) which bans nuclear-test explosions. So far the CTBT has been signed by 175 states, and ratified by 121. The UK and France were the first nuclear-weapon states to ratify the treaty. The facility at Eskdalemuir is to be upgraded to be an alternate primary IMS seismic station. The treaty requires that States Parties shall not interfere with the verification system, of which Eskdalemuir is an element.

The seismometer array at Eskdalemuir (EKA) (Figure 1) became operational on the 19 May 1962. The recording station comprises a recording laboratory, a seismological vault and an array of seismometers installed in pits spaced over an area 10 km square. The laboratory is situated on the eastern side of the Langholm-Innerleithen road (B709) about 30 km north of Langholm and 3 km north of the Eskdalemuir meteorological observatory. The seismological vault is about 400 m east south east of the laboratory, and the array lies to the east in the form of a cross with its centre, about 2.5 km from the laboratory. The latitude of the point of intersection of the two lines of the array is 55° 20' north and the longitude is 03° 09½' west. The array is situated across the watershed between tributary headstreams of the Teviot and Tweed flowing to the north-east, and headstreams of the Esk which generally flow to the south-west. The ground surface is largely open rolling moorland and forest plantations, which in is in many places peat covered. The altitude of the seismic pits varies from c 210 m to c 430 m. The isolated location ensures that microseismic interference is kept to a minimum. While there is very little light vehicular traffic on the Langholm-Innerleithen road logging trucks and heavy forestry machinery do use this road albeit intermittently.

Conclusions

At present there are no current, routinely implemented vibration mitigation technological solutions which can reduce the vibration from wind turbines. Technologies which are helpful in the reduction of vibration from mechanical systems ~~do~~ exist and in the long-term and at some additional cost it should be possible for manufacturers/developers to modify/augment these for application to wind turbines to reduce the levels of vibration transmitted into the ground.

However, the following conclusions are based on current turbine designs as built.

- 1 This analysis allows us to define an exclusion zone of 10 km within which **NO** windfarm/turbine development is acceptable
- 2 We recommend that in order to optimise total energy generation, it would be inadvisable to permit any additional windfarms of **current** design to be permitted within 17.5 km of Eskdalemuir as these will effectively sterilise the whole region from generating additional capacity.
- 3 It allows us to calculate that presently consented and planned windfarms as defined in Table 4, will not exceed the limit of 0.336 nm for approximately 80% of the time and that during the remaining 20% of the time where they *might* exceed the limit, the ambient background noise at Eskdalemuir will also be higher than the median value and as discrimination will be sub-optimal during these periods of higher windspeed this is acceptable.
- 4 Beyond 50 km, we do not anticipate that **ANY** reasonable windfarm development will have an impact on the detection capabilities of Eskdalemuir.
- 5 There is some limited headroom for additional capacity with currently available turbine designs *if* it is required, up to the aggregate noise level of 0.336 nm, but we would strongly recommend that in order to maximise the energy generation capability this takes place at distances greater than 25 km from Eskdalemuir. The algorithms developed here will permit this to be assessed.

Why the Taralga Windfarm Environmental Impact Statement – Noise Impact Assessment is critically flawed

Andrew Miskelly BCompSci*
January, 2005

* The meteorological content of this document has been viewed and verified by C. Arthur BSc (Hons), a qualified meteorologist currently employed by The Weather Co.

This document aims to illustrate why the Noise Impact Assessment (NIA) provided in the Environmental Impact Statement (EIS) for the Taralga Windfarm is flawed to the point that it has no real value. It will focus on the fact that the NIA has made an assumption which is only applicable a certain amount of the time. That assumption is that the wind speed at a reference height of 10 metres can be related to the wind speed at turbine height using a linear logarithmic equation, and can thus be used to calculate the likely noise output of turbines. It will show that the predicted noise output from turbines with respect to background noise on nearby premises has likely been underestimated in the NIA and will suggest that the proposal be rejected on these grounds, or at least that the NIA be repeated after more suitable input data has been acquired.

Introduction

The Environmental Impact Statement (EIS) for the Taralga Windfarm includes a Noise Impact Assessment (NIA) which is detailed in Appendix H. Appendix H states the following in its introduction (Taralga EIS, Appendix H, p1):

"[The NIA] describes the assessment of the likely acoustic impact of the proposed Taralga wind farm. Noise can have an effect on the environment and on the quality of life enjoyed by individuals and communities."

The NIA also correctly states the following, under the heading '1.5 Background Noise Survey' (Taralga EIS, Appendix H, p7):

"... background noise levels depend upon wind speed, as indeed do wind turbine noise emissions"

The NIA follows the guidelines set out in the 'Environmental Noise Guidelines - Wind Farms' (produced by the EPA-SA) and uses a method described in the 'Acoustic Report for a Wind Energy Converter Type NEG Micon NM 82/1650' to calculate the likely noise output of wind turbines.

The latter document describes how a method of calculating noise output of turbines was formed for which wind speed data at a height of 10 metres could be used as input. This involved calculating the 'standardised wind speed' at 10m using the actual wind speed at turbine height, which in this case was 96.5 metres (Acoustic Report - NM 82, p11), over a period of 4 hours during the day (Acoustic Report - NM 82, p7). Presumably the purpose of forming this method was to make noise assessments easier for prospective users of the turbine.

The NIA is summarised in Volume 1 of the EIS and states the following (Taralga EIS, Volume 1, p519):

"A unique characteristic of windfarms is that the noise level from each wind turbine increases as the wind speed at the site increases. As an offset, the background noise also generally increases under these conditions and masks the noise from the turbine."

Unfortunately both the method described by the NEG report and the statement made above are too simplistic for practical use in Taralga's case. This statement is only applicable a certain amount of the time but despite this it is the principle on which the integrity of the entire NIA depends.

The reason the statement is simplistic is that it assumes that the wind speed at a height of 10 metres (which is related to background noise) is related to the wind speed at turbine height (which is related to turbine noise - both aerodynamic and mechanical). This assumption does not account for all situations and is generally only applicable during daylight hours.

In fact it is very common for a meteorological condition to arise where the wind speed at the surface and at a height of 10 metres is nil or very light, but the wind speed at turbine height (69 metres in Taralga's case) remains well above cut-in speed. This condition is generally brought about by a nocturnal temperature inversion.

The effect of this is that there is no ambient noise at the surface as the wind has been displaced upwards by the inversion layer, but the turbine noise remains as wind speeds at turbine height are unaffected by the surface inversion.

The fact that the NIA does not address the occurrence of this condition is a major oversight. A strong and well defined nocturnal temperature inversion is extremely common all over the Tablelands due in part to their elevation and inland location. The result of this oversight is that the turbine noise figures produced in the NIA are likely to be badly underestimated at times when this condition occurs (generally at night when people are trying to sleep).

The nocturnal (radiation) temperature inversion

Nocturnal temperature inversions come about due to the land's ability to absorb solar heat during the day and radiate it rapidly after sunset.

During daylight hours the temperature profile of the planetary boundary layer (PBL) is maintained by deep convective mixing which occurs due to solar heating of the surface. This mixing breaks down any stratification (layers) that may form in the lower atmosphere and means that wind blows relatively uniformly throughout, though increasing with height as friction with the surface becomes less of a factor (this increase is known as 'wind gradient').

On reasonably sunny days where convective mixing is occurring, a logarithmic profile for wind speed is suitable.

After sunset the surface cools rapidly as heat is radiated back into the atmosphere. Through conduction, the surface layer (the lowest few metres) of the atmosphere also cools rapidly resulting in a shallow, stable and dense layer near the surface. Above this layer the temperature rises rapidly and the nocturnal inversion is formed. Because the inversion grows largely through conductive processes, it slowly increases in depth, with a maximum depth of some tens of metres usually reached just before dawn (at which time the effects of solar radiation will break down the inversion once more).

All frictional effects become confined to the shallow surface layer, and the atmosphere above this layer is decoupled from normal frictional effects. This results in near-surface winds becoming calm (or almost calm), while winds above the inversion remain at a similar speed to the pre-sunset surface winds. In fact it is not unusual for the winds above the inversion to accelerate because of the reduced friction on the bottom boundary (the inversion results in an almost 'free slip' bottom boundary condition for the flow – a condition associated with a well documented phenomenon known as the 'nocturnal jet')

The development of a nocturnal inversion is not dependent on near-calm conditions. While near-calm conditions will result in faster growth of the inversion, it is still common for the inversion to develop when wind speeds are significant. This is demonstrated below under the heading 'an example from the EIS' using data from Goulburn Airport automatic weather station

The nocturnal inversion has been recognised as a hazard to aviation at HMAS Albatross, Nowra. In a document entitled 'Winter Westerlies' the Station's Meteorological Officer states the following (Lutze, 2004):

'Cooling of the ground over night causes the lowest few hundred of feet of the atmosphere to cool, creating a temperature inversion near the surface. This inversion causes the winds at the surface to decouple from the winds above, creating large amounts of wind shear. This also creates a false impression of the upper wind conditions due to light winds at the surface.'

In situations where a nocturnal inversion has developed, it is not possible to relate a 10 metre wind speed to the wind speed above the inversion layer. A logarithmic profile will at the very least underestimate the wind speed drastically, and if the 10 metre winds are calm then the data is certainly unrepresentative.

Image 1 and image 2 graphically depict typical day time and night time conditions respectively.

Image 1

Image 1 shows a typical lower atmosphere during the day time and on less stable nights where a surface temperature inversion is not allowed to form. The lower atmosphere is mixed by convection that occurs during the day, thanks to solar heating of the surface. The wind blows right throughout the lower atmosphere and increases with height as friction with the surface becomes less of a factor. This increase with height is known as wind gradient

Image 2

Image 2 shows the situation on a stable night. After sunset the earth's surface commences radiation of heat back into the atmosphere. This radiation results in the formation of a layer of cold, dense, still air which grows in depth, upwards from the surface as the night progresses. This dense layer displaces the mixed, windy layer upwards until it is broken down once more by convection when the sun rises the following morning.

The scenario depicted in image 2 is most common under the following conditions:

- at inland locations, away from maritime influence
- at elevated locations where radiation into the atmosphere is more pronounced
- in winter when the surface is cold

The Taralga area and indeed the greater Tablelands meet both of the first two criteria which is why they are famous for cold, frosty nights and mornings in autumn, winter and spring (Foley, 1945, p17). Radiative frosts occur in the cold, still conditions underneath a temperature inversion.

The Noise Impact Assessment's assumption versus reality

The difference between the lower atmospheric conditions assumed by the NIA, and the conditions in reality with a surface temperature inversion in place are illustrated below

Image 3 – the assumed scenario

Description of Image 3 – the assumed scenario

Monitoring mast: The existing monitoring masts associated with the site stand at a height of 35 metres, though wind data for the noise assessment has been used from 10 metres.

House: In this example we will look at H10 – “Killarney” (Taralga EIS, Appendix H, p3).

Wind tower: The wind tower stands at a height of approximately 110 metres with the hub at 69 metres (Taralga EIS, Volume 1, p2.10).

Height in metres vs Wind speed: The graph shows in simple form (the relationship depicted is not logarithmic) the assumption that the NIA makes. That is, that wind speed is related to height and that the wind speed at hub height can be calculated from the wind speed at a lower anemometer height (10m). Thus it assumes that turbine noise output can be calculated using the 10m wind speed. This assumption is meteorologically unsound.

Image 4 – the actual scenario

Description of image 4 – the actual scenario

Monitoring mast: The bases of the monitoring masts associated with the site are all at an elevation of approximately 920 metres. One of these is located adjacent to T10 (Taraiga EIS, Vol. 1, figure 2.4)

House: H10 – “Killarney” – is at an elevation of 886 metres. It is located 513 metres to the north of wind tower T10 (Taraiga EIS, Appendix H, pp3-4)

Wind tower: The base of wind tower T10 is at an elevation of approximately 920 metres. It stands on a hill 513 metres to the south of H10. The blades of the wind tower are high enough above the surrounding terrain (up to 142m above H10) to be well clear of any surface temperature inversion, thus the turbine is operational.

Temperature inversion: A nocturnal, surface temperature inversion has formed, as described above.

By the early hours of the morning the cold, still layer underneath it has developed to a depth of around 50 metres. There is no ambient noise whatsoever around the house.

Above the temperature inversion a moderate wind is blowing. The wind turbines are operational

Height in metres vs Wind speed: The graph shows how the wind profile might appear through the lower atmosphere. Underneath the temperature inversion conditions are calm as the cold, dense air hugs the surface. Around the level of the temperature inversion the wind speed increases rapidly to the free atmospheric wind speed. Above the level of the temperature inversion the wind speed increases as consistent with the wind gradient.

What is demonstrated here is that under the conditions depicted by image 4 and described above, the method used by the NIA would have produced a 10 metre wind speed of zero, a background noise level of zero and a turbine noise output level of zero (due to its inclusion of 10 metre wind speed as a factor). In reality the 10 metre wind speed and hence background noise level were indeed both zero, but the turbine noise output level was above zero (due to the 69 metre wind speed being the required factor).

A real-life example from the EIS

Below is a graph which appears in the NIA (Taralga EIS, Appendix H, p17) It displays the measured background noise at H10 against the wind speeds at a height of 10 metres (around 44 metres above H10) measured nearby.

Image 5

Figure 1.5 Measured Background Noise Levels at Taralga – Phase 1

I have highlighted the period representing the night of July 2 (into July 3), 2004 for consideration. It is an example of what image 4 above depicts in action.

At time (1) – the evening of the 2nd – we see the background noise levels at H10 drop off rapidly. This is an indication that the sun has just set and the surface inversion has begun to form. At this time even the 10 metre winds are above turbine cut-in speed (approximately 4ms⁻¹ (Taralga EIS, Volume 1, p2.10), highlighted in red)

Between times (1) and (2) there is near-silence at H10 as the ground radiates heat and the inversion layer deepens but the wind speeds at 10 metres suggest that the wind speeds at 69 metres would certainly be strong enough for the turbines to remain operational.

At time (3) - the early hours of the morning of the 3rd - the inversion layer finally reaches 10m at the monitoring mast (44 metres higher than H10). The briefness of the period of calmness at the monitoring tower suggests that as in image 3 the inversion layer didn't get any deeper and the turbines were likely to be operational throughout the period. There is complete silence at H10.

At time (4) - mid-morning on the 3rd - the inversion layer finally breaks down and the fog clears as the ground is heated once more by the sun. The winds that have been present above the inversion layer all along are once again allowed to mix back down to the surface and ambient noise returns at H10.

The data in the graph confirms that this pattern is quite common, particularly that data in the final week of the survey. Note that the survey only spans a little over a fortnight.

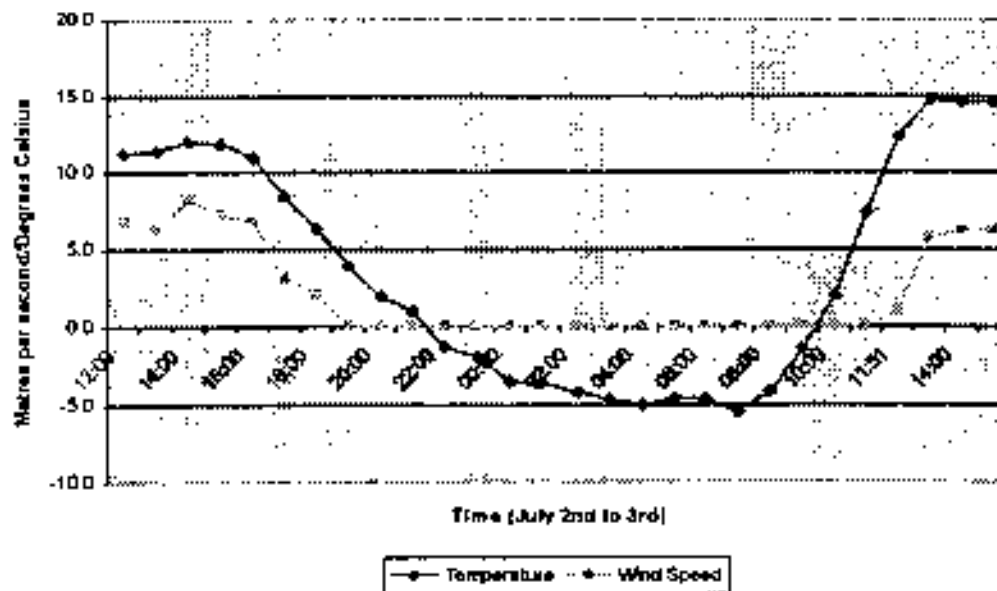

For extra background I have included and summarised some independent and more detailed meteorological observations from both the Taralga Post Office manual weather station and the Goulburn Airport automatic weather station for 2nd and 3rd (Bureau of Meteorology)

Firstly, the observations from Taralga Post Office are noted and summarised below.

Time	Weather	Summary
9am, July 2	Weather: None. Wind: Moderate westerly Temperature: 7.4°C	This indicates that winds were present during the 2 nd . These winds are displaced upwards some tens of metres overnight by the surface inversion
Daytime, July 2.	Maximum temperature: 11°C	1°C above average.
Nighttime, July 2.	Minimum temperature: -4°C	The severity of the frost indicates that a deep surface inversion formed.
9am, July 3.	Weather: Fog clearing. Wind: Calm Temperature: 0.5°C	The clearing fog and the temperature both indicate that the inversion is still breaking down. The timing is consistent with the indications of the graph in image 5

Secondly, the temperature and wind speed at a height of 10 metres at Goulburn Airport are graphed below for the period between midday on July 2 and 15:00 on July 3. This data shows the 10 metre winds becoming calm overnight as the nocturnal inversion and associated frost form, and returning late in the morning as the inversion breaks down

Gouburn Ap AWS 27/2004 12:00 - 27/2004 15:00

Conclusion

The validity of the information provided above, the detail supplied in the document entitled 'Effects of the wind profile at night on wind turbine sound' and the plight of many windfarm affected residents both in Australia and abroad all indisputably suggest that the results of Noise Impact Assessments being provided by developers are critically flawed.

In Taralga's case I would suggest given the proximity of neighbours to landowners signed up with the developer that the noise issue cannot possibly be addressed satisfactorily. This then is enough reason to reject the development.

At least I would recommend that the Department demand a more adequate Noise Impact Assessment from the developer, specifying that it include input wind measurements taken at the proposed turbine height. This way there is no speculation and it is less likely that we will repeat mistakes that have been made elsewhere.

The following is a comment I sent to the EPA-SA regarding their 'Environmental Noise Guidelines: Wind Farms'. The communication was not responded to.

*Attn: Information Officer
Environment Protection Authority*

I would like to make a comment on the document entitled 'Environmental Noise Guidelines: Wind Farms' (ISBN 1 876562 43 9) which you published in February 2003 and would appreciate a response including any remarks or explanations you may have.

My comment relates to the practice of using wind speed data at a height of 10 metres for establishing both background noise levels and wind farm turbine noise levels, as prescribed by your document.

The validity of this practice appears to rely on the idea that wind speed at turbine height (say 70 metres) can be calculated from the wind speed at 10 metres using a linear equation. Using this idea, one could go on to assume that when the wind speeds lower at 10 metres the noise generated by a turbine also lowers. This idea is meteorologically unsound.

In fact, a scenario where the wind speed at 10 metres and below is zero and the wind speed at turbine height is above turbine cut-in (say 3.5 metres per second) is common - particularly at inland locations, at night and during winter.

This scenario generally comes about due to nocturnal radiation of heat from the earth's surface causing the formation of a cold, still layer near the surface underneath a temperature inversion. The depth of this layer is often such that background noise at the surface in the area of wind turbines is nil but turbine noise remains significant. The depth of this still layer would seldom ever reach turbine height.

Your noise guidelines do not appear to address this likelihood

I would appreciate your comments on this matter including whether or not you consider your guidelines suitable for locations outside of South Australia.

*Kind regards,
Andrew Miskelly*

IEC 61400-Wind Turbine Generator Systems
 Part 11 – Acoustic Noise Measurement Techniques

- **Annex A – Other possible characteristics of wind turbine noise emission and their quantification (page 35)**

A disturbance can be caused by low-frequency noise with frequencies in the range from 20 to 100 Hz. The annoyance caused by noise dominated by low frequencies is often not adequately described by the A-weighted sound pressure level, with the result that nuisance of such a type may be underestimated if assessed using only an LAeq value.

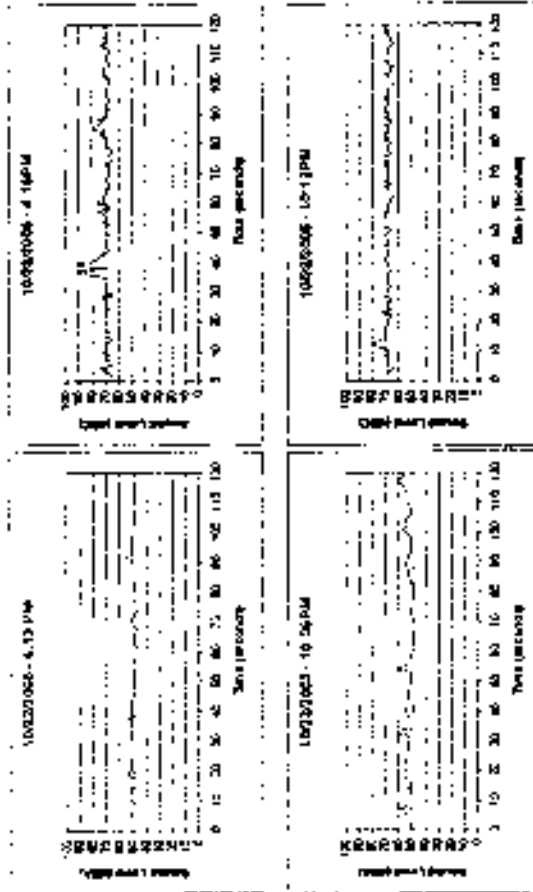

It may be possible to decide whether the noise emission can be characterized as having a low-frequency component. This is likely to be the case if the difference between the k and C-weighted sound pressure levels exceeds approximately 20 dB.

In these circumstances, low-frequency noise may be quantified by selecting the one-third octave band measurements described in the main body of the text, down to 20 Hz. For other third octave bands, the 20, 25, 31.5 and 40 Hz bands should additionally be determined.

dB Weighing

One-day Noise Measurements

© O. A. Soyak

Lycoming County Hearing

Subjective Issues

- A listener's ability to hear noises depend on many subjective factors
- The turbine noise is distinguished from the random background noise because of its periodic characteristic
- Wind speed in the ground level usually do not correlate to the wind speed at the height of the turbine
- A lower level masking noise in the ground level affect the listener's ability to hear the turbine noise

(C) O A. Sykes

Lycoming County Hearing

14

Conclusions

- Recorded wind mill noise contains dominant low frequency components below 100 Hz
- Recordings clearly show the noise is distinguished from the background noise due to its periodic characteristic
- The noise level difference between A and C weighing is approximately 20 dB
- A weighing does not represent adequately the wind turbine noise
- C weighing noise level measurements indicate that the noise level at 0.55 mile distance exceeds the Lycoming County Zoning ordinance

Effects of the wind profile at night on wind turbine sound

G.P. van den Berg*

Science Shop for Physics, University of Groningen, Nijenborgh 4, 9747 AG Groningen, Netherlands

Received 22 January 2003; accepted 22 September 2003

Abstract

Since the start of the operation of a 30 MW, 17 turbine wind park, residents living 500 m and more from the park have reacted strongly to the noise; residents up to 1900 m distance expressed annoyance. To assess actual sound immission, long term measurements (a total of over 400 night hours in 4 months) have been performed at 400 and 1500 m from the park. In the original sound assessment a fixed relation between wind speed at reference height (10 m) and hub height (98 m) had been used. However, measurements show that the wind speed at hub height at night is up to 2.6 times higher than expected, causing a higher rotational speed of the wind turbines and consequentially up to 15 dB higher sound levels, relative to the same reference wind speed in daytime. Moreover, especially at high rotational speeds the turbines produce a ‘thumping’, impulsive sound, increasing annoyance further. It is concluded that prediction of noise immission at night from (tall) wind turbines is underestimated when measurement data are used (implicitly) assuming a wind profile valid in daytime.

1. Introduction

In Germany several wind turbine parks have been and are being established in sparsely populated areas near the Dutch border. One of these is the Rhede Wind Park in northwestern Germany with seventeen 1.8 MW turbines of 98 m hub height and with 3-blade propellers of 35 m wing length. The turbines have a variable speed increasing with wind speed, starting with 10 r.p.m. (revolutions per minute) at a wind speed of 2.5 m/s at hub height up to 22 r.p.m. at wind speeds of 12 m/s and over.

At the Dutch side of the border is a residential area along the Oude Laan and Veendijk (see Fig. 1) in De Leije: countryside dwellings surrounded by trees and agricultural fields. The dwelling nearest to the wind park is some 500 m west of the nearest wind turbine (W 16).

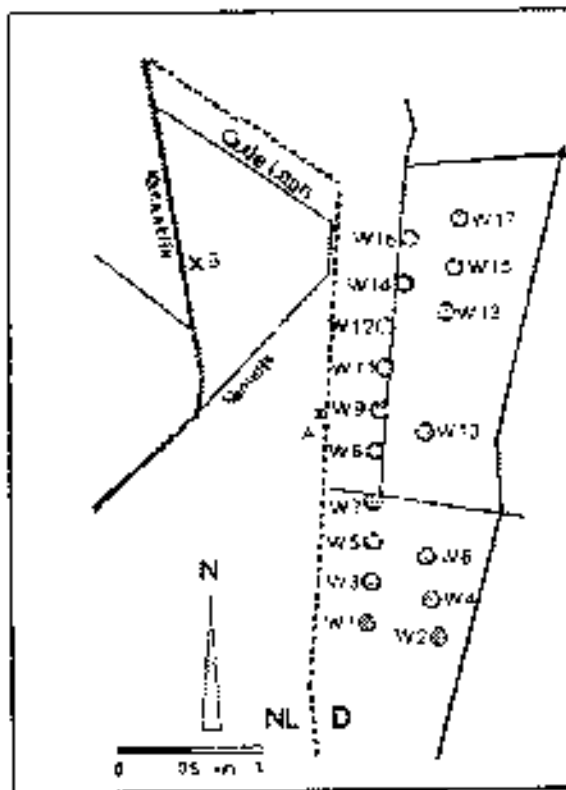

Fig. 1. Location of wind turbines (W_n) and immission measurements (A and B) near the Dutch/German (NL/D) border.

According to a German noise assessment study a maximum immission level of 43 dB(A) was expected, 2 dB below the applied German noise limit. According to a Dutch consultancy immission levels would comply with Dutch (wind speed dependent) noise limits.

After the park was put into operation residents made complaints about the noise, especially at (late) evening and night-time. The residents, united in a neighbourhood group, could not persuade the German operator to put in place mitigation measures or to carry out an investigation of the noise problem and brought the case to court. The Science Shop for Physics had just released a report explaining a possible discrepancy between the calculated and the actual sound immission levels of the wind turbines because of changes in wind profile, and was asked to investigate the consequences of this discrepancy by sound measurements. Although at first the operator agreed to supply measurement data from the wind turbines (such as power output, rotation speed, axle direction), this was withdrawn after the measurements had started. All relevant data therefore had to be supplied or deduced from the author's own measurements.

2. Noise impact assessment

In the Netherlands and Germany noise impact on dwellings near a wind turbine or wind turbine park is calculated with a sound propagation model. Wind turbine sound power levels L_{wT} are used

as input for the model, based on measured or estimated data. In Germany a single 'maximum' sound power level (at 95% of maximum electric power) is used to assess sound impact. In the Netherlands sound power levels related to wind speeds at 10 m height are used; the resulting sound immission levels are compared to wind speed-dependent noise limits. Implicitly this assessment is based on measurements in daytime and does not take into account atmospheric conditions affecting the wind profile, especially at night.

In the Netherlands a national calculation model is used [1] to assess noise impact, as is the case in Germany [2]. According to Kerckers [3] there are, at least in the case of these wind turbines, no significant differences between both models.

In both sound propagation models the sound immission level L_{imm} at a specific observation point is a summation over j sound power octave band levels L_{Wj} of k sources (turbines), reduced with attenuation factors D_{jk} :

$$L_{imm} = 10 \log \left[\sum_j \sum_k 10^{(L_{Wj} - D_{jk})/10} \right] \quad (1)$$

where L_{Wj} , assumed to be identical for all k turbines, is a function of rotational speed. D_{jk} is the attenuation due to geometrical spreading (D_{geo}), air absorption (D_{air}) and ground absorption (D_{ground}); $D_{jk} = D_{geo} + D_{air} + D_{ground}$.

Eq. (1) is valid for a downwind situation. For long-term assessment purposes a meteorological correction factor is applied to (1) to account for an 'average atmosphere'. When comparing calculated and measured sound immission levels in this study no such meteo-correction is applied.

3. Wind turbines noise perception

There is a distinct audible difference between the night and daytime wind turbine sound at some distance from the turbines. On a summer's day in a moderate or even strong wind the turbines may only be heard within a few hundred metres and one might wonder why residents should complain of the sound produced by the wind park. However, on quiet nights the wind park can be heard at distances of up to several kilometres when the turbines rotate at high speed. On these nights, certainly at distances between 500 and 1000 m from the wind park, one can hear a low pitched thumping sound with a repetition rate of about once a second (coinciding with the frequency of blades passing a turbine mast), not unlike distant pile driving, superimposed on a constant broadband 'noisy' sound. A resident living at 1.5 km from the wind park describes the sound as 'an endless train'. In daytime these pulses are not clearly audible and the sound is less intrusive or even inaudible (especially in strong winds because of the then high ambient sound level).

In the wind park the turbines are audible for most of the (day and night) time, but the thumping is not evident, although a 'swishing' sound—a regular variation in sound level caused by the pressure variation when a blade passes a turbine mast—is readily discernible. Sometimes a rumbling sound can be heard, but it is difficult to assign it, by ear, to a specific turbine or to assess its direction.

4. Stability-dependent wind profiles

Usually a fixed relation is assumed between the wind speed v_h at height h and the wind speed v_{ref} at a reference height h_{ref} (usually 10 m), which is the widely used logarithmic wind profile with surface roughness z as the only parameter. See for example the international recommendations for wind turbine noise emission measurements [4,5]. For height h the wind speed v_h is calculated as follows:

$$v_h = v_{ref} \log(h/z) / \log(h_{ref}/z). \quad (2)$$

This equation is an approximation of the wind profile in the turbulent boundary layer of a neutral atmosphere, when the air is mixed by turbulence resulting from friction with the surface of the earth. During daytime thermal turbulence is added, especially when the heating of the earth surface by the sun is significant. At night-time a neutral atmosphere, characterized by the adiabatic temperature gradient, occurs under heavy cloud and/or at relatively high wind speeds. When there is some clear sky and in the absence of strong winds the atmosphere becomes stable because of radiative cooling of the surface: the wind profile changes and can no longer be adequately described by Eq. (2). The effect of the change to a stable atmosphere is that, relative to a given wind speed at 10 m height in daytime, at night there is a higher wind speed at hub height and thus a higher turbine sound power level; also there is a lower wind speed below 10 m and thus less wind-induced sound in vegetation. According to measurements by Holtslag [6] in a non-neutral atmosphere (either stable or unstable) a correction must be added to the logarithmic terms in the wind profile according to Eq. (2):

$$v_h = v_{ref} [\log(h/z) - \Psi_m] / [\log(h_{ref}/z) - \Psi_m], \quad (3)$$

where $\Psi_m = \Psi_m(h/L)$ is a rather elaborate function of height h and Monin–Obukhov length L . L is a stability measure and is positive for a stable, negative for an unstable atmosphere; for a neutral atmosphere L is a large number, either positive or negative. For calculations of sound propagation in the atmosphere Kühner [7] proposes a simple equation used in the German Air Quality Guideline “TA-Luft” [8]:

$$v_h = v_{ref} (h/h_{ref})^m, \quad (4)$$

where m is a number that depends on stability.

Stability can be categorized in Pasquill classes that depend on observations of wind speed and cloud cover (see, e.g. Ref. [9]). They are usually referred to as classes A (very unstable) through F (very stable). In “TA-Luft” a closely related classification is given (again closely related, according to Kühner [7], to the international Turner classification). An overview of stability classes with the appropriate value of m is given in Table 1. In Fig. 2 wind profiles are given as measured by Holtslag [6], as well as wind profiles according to Eqs. (2) and (4).

According to long-term data from Eelde and Leeuwarden [10], two meteorological measurement sites of the KNMI (Royal Dutch Meteorological Institute) in the northern part of the Netherlands, a stable atmosphere (Pasquill classes E and F) at night occurs for a considerable proportion of night-time: 34% and 32%, respectively.

According to Eq. (2) the ratio of wind speed at hub height (98 m) to wind speed at reference height, over land with low vegetation ($z = 3$ cm), would be $f_{log} = v_{98}/v_{10} = 1.4$. According to

Table 1
Stability classes and factor m

Pasquill class	Name	Comparable stability class "TA-Luft" [8]	m
A	Very unstable	V	0.09
B	Moderately unstable	IV	0.20
C	Neutral	III	0.22
D	Slightly stable	II	0.28
E	Moderately stable	I	0.37
F	(Very) stable	I	0.41

Fig. 2. Measured wind profiles (thin lines, (6)) and wind profile according to TA Luft (dotted line, (8)) in a stable atmosphere, and wind profile according to logarithmic model of formula 2 with $z = 3$ cm (bold line).

Eq. (4) and Table 1 this ratio would be 1.2 in a very unstable atmosphere and $f_{stab} = 2.5 = 1.8f_{100}$ in a (very) stable atmosphere.

The fact that wind speeds at 10 m height may not be a good, unique predictor for hub height wind speeds has been put forward by Rudolphi [11]. He concluded from measurements that wind speed at 10 m height is not a good measure for wind turbine sound power: according to his measurements near a 58 m hub height wind turbine at night the turbine sound level was 5 dB higher than expected. This conclusion was not followed by a more thorough investigation.

The question addressed in this study is: what is the influence of the change in wind profile on the sound immission near (tall) wind turbines?

5. Measurement method

Sound immission measurements were made over 1435 hours, of which 417 hours were at night, within four months at two consecutive locations with an unmanned Sound and Weather

Measurement System (SWMS) consisting of a type 1 sound level meter with a microphone at 4.5 m height with a 9 cm diameter foam wind shield, and a wind meter at 10 m as well as at 2 m height. Every second, wind speed and wind direction (at 10 and 2 m height) and the A-weighted sound level were measured; the measured data are stored as statistical distributions over 5 min intervals. From these distributions all necessary wind data and sound levels can be calculated, such as average wind speed, median wind direction or equivalent sound level and any percentile (steps of 5%) wind speed, wind direction or sound level, in intervals of 5 min or multiples thereof.

Also complementary measurements were done with logging types 1 and 2 sound level meters and a type 1 spectrum analyzer to measure immission sound levels in the residential area over limited periods ([12], not reported here), and emission levels near the wind turbines. Emission levels were measured according to international standards [4,5], but for practical purposes the method could not be adhered to in detail; with respect to the recommended values a smaller reflecting board was used for the microphone ($30 \times 44 \text{ cm}^2$ instead of a 1 m diameter circular board) and a smaller distance to the turbine (equal to tower height instead of tower height + blade length); reasons for this are given in a separate paper [13]. Also it was not possible to carry out emission measurements with only one turbine in operation.

6. Results: sound emission

Emission levels L_{eq} measured very close to the centre of a horizontal, flat board at a distance R from a turbine hub can be converted to a turbine sound power level L_W [4,5]:

$$L_W = L_{eq} - 6 + 10 \log(4\pi R^2). \quad (5)$$

From earlier measurements [3] a wind speed dependence of L_W was established as given in Table 2. As explained above, the wind speed at 10 m height is not considered a reliable single measure for the turbine sound power. Rotational speed is a better measure.

Emission levels have been measured, typically for 5 min per measurement, at nine turbines on seven different days with different wind conditions. The results are plotted in Fig. 3; the sound power level is plotted as a function of rotational speed N . N is proportional to wind speed at hub height and could be determined by counting, typically during 1 min, blades passing the turbine mast. This counting procedure is not very accurate (accuracy per measurement is ≈ 2 counts, corresponding to 2/3 r.p.m.) and is probably the dominant reason for the spread in Fig. 3. The best logarithmic fit to the data points in Fig. 3 is

$$L_W = 67.1 \log(N) + 15.4 \text{ dB(A)} \quad (6)$$

with a correlation coefficient of 0.98. The standard deviation of measurement values with respect to this fit is 1.0 dB.

Table 2
Sound power level of wind turbines [3]

Wind speed v_{10}	m/s	5	6	7	8	9	10
Sound power level L_W	dB(A)	94	96	98	101	102	103

At the specification extremes of 10 and 22 r.p.m. the (individual) wind turbine sound power level L_W is 82.8 and 105.7 dB(A), respectively.

In Table 3 earlier measurement results [3] are given for the octave band sound power spectrum. Also in Table 3 the results of this study are given: the logarithmic average of four different spectra at different rotational speeds. In all cases spectra are scaled, with Eq. (6), to the same sound power level of 103 dB(A).

To calculate sound immission levels at a specific rotational speed (or vice versa) the sound power level given in Eq. (6), and the spectral form in Table 3 ('this study') have been used.

7. Results: sound immission

The sound immission level has been measured with the unmanned SWMS on two locations. Between May 13 and June 22, 2002 it was placed amidst open fields with barren earth and later low vegetation 400 m west of the westernmost row of wind turbines (location A, see Fig. 1). This site was a few metres west of the Dutch–German border, visible as a ditch and a 1.5–2 m high dike. Between June 22 and September 13, 2002 the SWMS was placed on a lawn near a dwelling 1500 m

Fig. 3. Measured wind turbine sound power level L_W as a function of turbine rotational speed N

Table 3
Octave band spectra of wind turbines at $L_W = 103$ dB(A)

Frequency	Hz	63	125	250	500	1000	2000	4000	L_W
This study	dB(A)	82	92	94	98	98	93	88	103
[3]	dB(A)	85	91	95	98	98	92	83	103

west of the westernmost row (location B), with both low and tall trees in the vicinity. On both locations there were no reflections of turbine sound towards the microphone, except via the ground, and no objects (such as trees) between the turbines and the microphone, except via the possible wind induced sound in vegetation relevant sound sources are traffic on rather quiet roads, agricultural activities, and birds. As, because of the trees, the correct (potential) wind speed and direction could not be measured on location B, wind measurement data provided by the KNMI were used from their Nieuw Beerta site 10 km to the north. These data fitted well with the measurements on location A.

At times when the wind turbine sound is dominant, the sound level is relatively constant within 5 min intervals. In Fig. 4 this is demonstrated for two nights. Thus measurement intervals with dominant turbine sound could be selected with a criterion based on a low variation in sound level: $L_5 - L_{95} \leq 4 \text{ dB}$, where L_5 and L_{95} are 5 and 95 percentile sound level. In a normal (Gaussian) distribution this would equal $\sigma \leq 1.2 \text{ dB}$, with σ the standard deviation.

On location A, 400 m from the nearest turbine, the total measurement time was 371 h. For 25% of this time the wind turbine sound was dominant, predominantly at night (72% of all 105 nightly hours) and hardly during daytime (4% of 191 h) (see Table 4).

At location B, 1500 m from the nearest turbine, these percentages were almost halved, but the turbine sound remained dominant for over one-third of the time at night (38% of 312 h). The trend in percentages agrees with complaints mostly concerning noise in the (late) evening and at night and their being more strongly expressed by residents closer to the wind park.

In Fig. 5 the selected (i.e., with dominant wind turbine sound) 5 min equivalent immission sound levels $L_{eq,5 \text{ min}}$ are plotted as a function of wind direction (left) and of wind speed (right) at 10 m height, for both location A (above) and B (below). It is not clear why the KNMI wind speed data (used for location B) cluster around integer values of the wind speed.

Also the wind speed at 10 and 2 m height at location A are plotted (in 5A and 5B, respectively), and the local wind speed (influenced by trees) at 10 m at location B (5C). The immission level data points are separated in two classes where the atmosphere was stable or neutral, according to

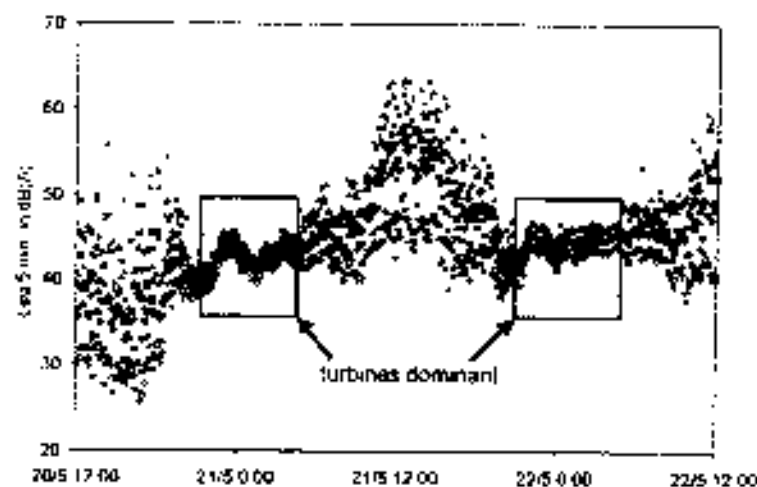

Fig. 4. 48 h registration of immission level ($L_5 = \Delta$; $L_{95} = \blacksquare$; $L_{95} = \circ$) per 5 min at location A; turbines are considered the dominant sound source if $L_5 - L_{95} \leq 4 \text{ dB}$.

Table 4
Total measurement time in hours and selected time with dominant wind turbine sound

Location	Total time	Night 23:00–6:00	Evening 19:00–23:00	Day 6:00–19:00
A: Total	371	105	75	191
A: Selected	92	76	9	7
	25%	72%	12%	4%

B: Selected	136	119	13	4
	13%	38%	7%	0.7%

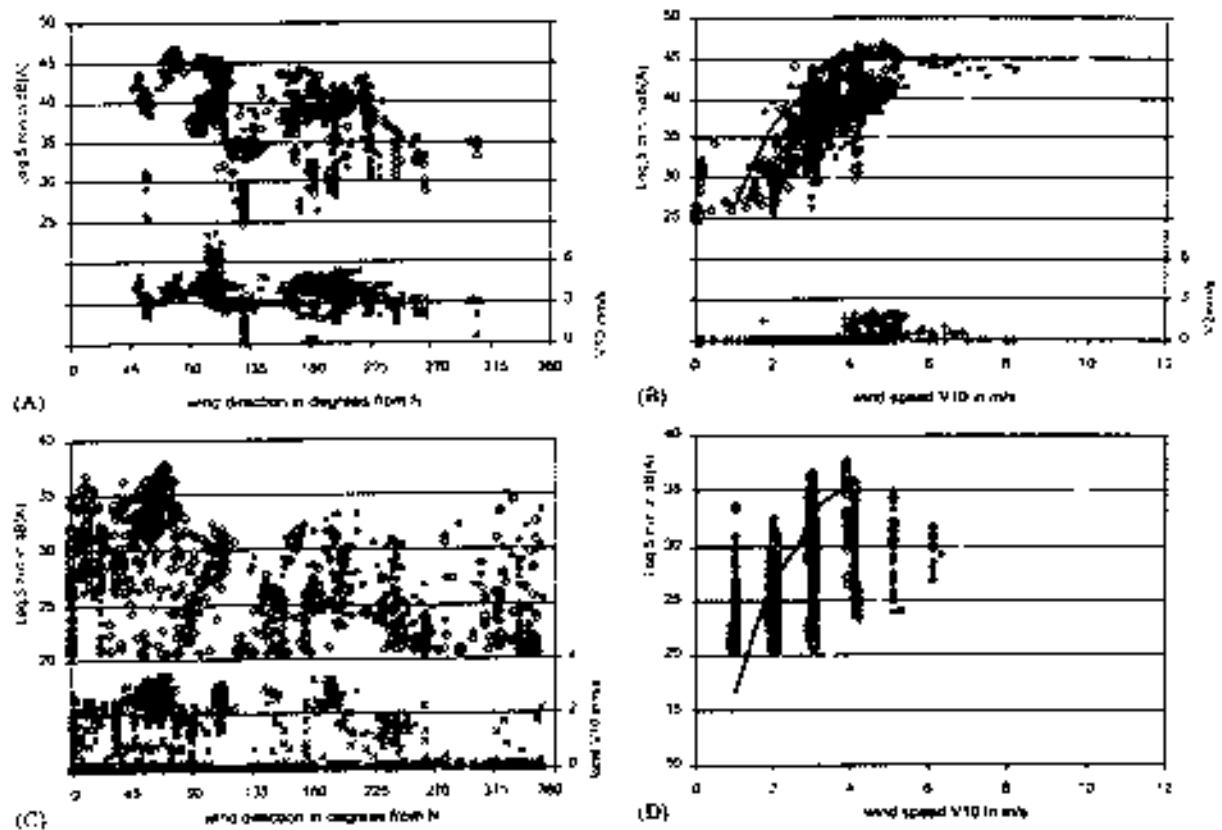

Fig. 5. Measured sound levels $L_{log,5,10m}$ at locations A (above) and B (below) as a function of median wind direction (left) and average wind speed (right) at reference height (10 m), separated in classes where the atmosphere at Eelde was observed as stable (\diamond) or neutral (\bullet). Also plotted are expected sound levels according to logarithmic wind profile and wind speed at reference height (grey lines in B and D), and at a 2.6 higher wind speed (black lines in B and D). Figures A, B and C also contain the wind speed v_{10} (A), v_5 (B), and the local v_{10} (C) disturbed by trees, respectively.

observations of wind speed and cloud cover at Eelde. Eelde is the nearest KNMI site for these observations, but it is 40 km to the west, so not all observations will be valid for the area of the study.

In Fig. 5B a grey line is plotted connecting calculated sound levels with sound power levels according to Table 2 (the lowest value at 2.5 m/s is extrapolated [12]), implicitly assuming a fixed logarithmic wind profile according to Eq. (2). If this line is compressed in the direction of the abscissa with a factor 2.6, the result is a (black) line coinciding with the highest 1-h values ($L_{eq,1h}$) at each wind speed. Apparently, at these immission levels, the wind speed is 2.6 times higher than expected. In Fig. 6 this is given in more detail: all 5 min measurement periods that satisfied the L_5 - L_{95} -criterion, with at least 4 periods per hour, were taken together in consecutive hourly periods and the resulting $L_{eq,T}$ ($T = 20-60$ min) was calculated. These 83 $L_{eq,T}$ -values are plotted against the average wind speed v_{10} over the same time T . Also plotted in Fig. 6 are: the expected immission levels calculated from (1), implicitly assuming a logarithmic wind profile according to (2), so $f_{log} = 1.4$; the immission levels assuming a stable wind profile (4) with $m = 0.41$, so $f_{stable} = 2.5 = 1.8 \cdot f_{log}$; the maximum immission levels assuming $f_{max} = 3.7 = 2.6 \cdot f_{log}$, in agreement with a wind profile (4) with $m = 0.57$. The best fit of all data points ($L_{eq,T}$) in Fig. 6 with $1 < v_{10} < 5.5$ m/s is $L_{eq,T} = 32 \cdot \log(v_{10}) + 22$ dB (correlation coefficient 0.80); this fit agrees within 0.5 dB with the expected level according to the stable wind profile. The best fit of all 5 min data-points in Fig. 5B yields the same result.

Thus on location A the highest one hour averaged wind speeds at night are 2.6 times the expected values according to the logarithmic wind profile in Eq. (2). As a consequence, sound levels at (during night-time) frequently occurring wind speeds of 3 and 4 m/s are up to 15 dB higher than expected, 15 dB being the vertical distance between the expected and highest 1-h immission levels at 3-4 m/s (upper and lower lines in Figs. 5B and 6).

The same lines as in 5B, but valid for location B, are plotted in Fig. 5D; immission levels here exceed the calculated levels, even if calculated on the basis of a 2.6 higher wind speed at hub height. This is the result of shortcomings of the calculation model for long distances, at least for

Fig. 6. Measured sound levels $L_{eq,T}$ ($T = 20-60$ min) at location A with best fit: (1) expected sound levels according to a logarithmic wind profile ($v_{98}/v_{10} = f_{log} = 1.4$; dotted line), a stable wind profile ($v_{98}/v_{10} = 1.8 \cdot f_{log}$; thick grey line) and maximum wind speed ratio ($v_{98}/v_{10} = 2.6 \cdot f_{log}$; thin line).

night-time conditions: from the long-term measurements at location B and short term (one night) at other locations ([12], not reproduced here) it follows that sound immission levels calculated according to the standard model used in the Netherlands [1], underestimate measured levels at night with ca. 1 dB at distances of 550–1000 m increasing to about 3 dB at distances up to 1900 m.

As is clear from the wind speed at 2 m height plotted in Fig. 5B, there is only a very light wind near the ground even when the turbines rotate at high power. This implies that in a quiet area with low vegetation the ambient sound level may be very low. The contrast between the turbine sound and the ambient sound is therefore higher at night than during the daytime.

Although at most times the wind turbine sound dominates the sound levels in Fig. 5, it is possible that at low sound levels, i.e., at low rotational speeds and low wind speeds, the L_N – L_{95} -criterion is met while the sound level is not entirely determined by the wind turbines. This is certainly the case at levels close to 20 dB(A), the sound level meter noise floor.

The long-term night-time ambient background level, expressed as the 95-percentile (L_{95}) of all measured night-time sound levels on location B, was 23 dB(A) at 3 m/s (v_{10}) and increasing with $3.3 \text{ dB} \cdot (\text{m s}^{-1})^{-1}$ up to $v_{10} = 8 \text{ m/s}$ [12]. Comparing this predominantly non-turbine background level with the sound levels in Figs. 5B and D, it is clear that the lowest sound levels may not be determined by the wind turbines, but by other ambient sounds (and instrument noise). This wind speed dependent, non-turbine background sound level L_{95} is, however, insignificant with respect to the highest measured levels. Thus, the high sound levels do not include a significant amount of ambient sound not coming from the wind turbines. This has also been verified on a number of evenings and nights by personal observation.

8. Comparison of emission and immission sound levels

From the 30 measurements of the equivalent sound level $L_{eq,T}$ (with T typically 5 min) measured at distance R from the turbine hub (R typically $100\sqrt{2}$ m), a relation between sound power level L_W and rotational speed N of a turbine could be determined: see Eq. (6).

This relation can be compared with the measured immission sound level $L_{i,T}$ ($T = 5$ min) at location A, 400 m from the wind park (closest turbine), in 22 cases where the rotational speed was known. These measurements were taken at different times to the emission measurements. The best logarithmic fit for the data points of the immission sound level L_{imm} as a function of rotational speed N is

$$L_{imm} = 57.6 \log(N) + 30.6 \text{ dB(A)} \quad (7)$$

with a correlation coefficient of 0.92 and a standard deviation of 1.5 dB. Both relations from Eqs. (6) and (7) and the data points are given in Fig. 7. The difference between both relations is $L_W - L_{imm} = 9.5 \log(N) + 46.0 \text{ dB}$. For the range 14–20 r.p.m., where both series have data points, the average difference is 57.9 dB, the maximum deviation from this average is 0.8 dB (14 r.p.m.: 57.1 dB(A); 20 r.p.m.: 58.6 dB(A); see lower part of Fig. 7). It can be shown by calculation that about half of this deviation can be explained by the variation of sound power spectrum with increasing speed N .

The sound immission level can be calculated using Eq. (1). For location A, assuming all turbines have the same sound power L_W , this leads to $L_W - L_{imm} = 58.0 \text{ dB}$. This is independent

Fig. 7. Turbine sound power levels L_w measured near wind turbines (●) and immission levels L_{imm} measured at 400 m from wind park (○); averages diff: 57.9 dB; (below) increase of difference $L_w - L_{imm}$ with rotational speed

of sound power level or rotational speed, as it is calculated with a constant spectrum averaged over several turbine conditions, i.e., speeds. The measured difference (57.9 dB) matches very closely the calculated difference (58.0 dB).

The variation in sound immission level at a specific wind speed v_{10} in Figs. 5B and D is thus seen to correspond to a variation in rotational speed N , which in turn is related to a variation in wind speed at hub height, not to a variation in v_{10} . At location A, N can be calculated from the measured immission level with the help of Eq. (7) or its inverse form $N = 3.4 \times 10^{L_{imm}/57.6}$.

9. Effect of atmospheric stability

In Fig. 5 measurement data have been separated into two sets according to atmospheric stability in Pasquill classes, supplied by KNMI from their measurement site Eelde, 40 km to the west of our measurement site. Although the degree of stability will not always be the same for Eelde and our measurement location, the locations will correlate to a high degree in view of the relatively small distance between them. For night-time conditions 'stable' refers to Pasquill classes E and F (lightly to very stable) and corresponds to $V_{10} \leq 5$ m/s and cloud coverage $C \leq 50\%$ or $V_{10} \leq 3.5$ m/s and $C \leq 75\%$, 'neutral' (class D) corresponding to all other situations. Although from Fig. 5 it is clear that the very highest sound levels at an easterly wind ($\approx 80^\circ$) do indeed occur

in stable conditions, it is also clear that in neutral conditions too the sound level is higher than expected for most of the time, the expected values corresponding to the grey lines in Figs. 5B and D, derived from daytime conditions. According to this study the sound production, and thus wind speed, at 100 m height is often higher than expected at night, in a stable, but also in a neutral atmosphere. On the other hand, even in stable conditions sound levels may be lower than expected (i.e., below the grey lines), although this rarely occurs. It may be concluded from these measurements that a logarithmic wind profile based only on surface roughness does not apply to the night-time atmosphere in our measurements, not in a stable atmosphere and not always in a neutral atmosphere.

10. Impulsive sound

At night the sound from the wind park contains repetitive pulses, unlike the sound in daytime. According to the long-term auditory observation of residents this pulse-like character or 'thumping', is more pronounced and more annoying at high turbine rotational speed. Fig. 8 shows a recording of the sound pressure level every 50 ms over a 180 s period, taken from a DAT-recording on a summer night (June 3, 0:40 h) on a terrace of a dwelling at 750 m west of the westernmost row of wind turbines (this sound includes the reflection on the façade at 2 m). There is a slow variation of the 'base line' (minimum levels) probably caused by variations in wind speed and atmospheric sound transmission. There is furthermore a variation in dynamic range: a small difference between subsequent maximum and minimum levels of less than 2 dB is alternated by larger differences. In the lower part of Fig. 8 part of the sequence is amplified and shows at first a somewhat irregular pattern of dynamic range 1-1.5 dB leading to a more regular pattern of a pulse every second with a pulse height of 3-4 or 5-6 dB. This pattern is compatible with a complex of three pulse trains with pulse height of about 1 dB and slightly different repetition frequencies.

Fig. 8. Sound pressure level caused by wind turbines per 50 ms near dwelling at 750 m from nearest turbine (including reflection at façade at 2 m) over a 3 min period; part of the sequence is amplified below.

of about 1 Hz. When the pulses are out of phase (around 150 s in Fig. 8), there are only 1 dB variations. When 2 of them are in phase (around 160 s) pulse height is doubled (+ 3 dB), and tripled (+ 5 dB, 170 s) when all three are in phase. The rotational speed of the turbines at the time was 20 r.p.m., so the repetition rate of blades passing a mast was 1 Hz.

The low number of pulse trains, compared to 17 turbines, is compatible with the fact that only a few turbines dominate the sound immission at this location. The calculated immission level is predominantly caused by two wind turbines (numbers 11 and 12; see Fig. 1, contributing 35% of the A-weighted sound energy), less by two others (9 and 14; 21%), so only 4 turbines contribute more than half of the sound immission energy.

A pulse-like character was not expected; e.g., in a recent Dutch report [14] it was stated that wind turbines do not produce impulsive noise. However, when measurements are made at a single turbine, as is usual, no pulses will be audible according to the explanation given above.

11. Annoyance

The immission sound level at location A is for most of the time (at least 72% of night-time hours) higher than expected. At the most frequent night-time wind speeds (v_{10}) of 3 and 4 m/s the sound level is up to 15 dB more than expected. Also at location B, at a considerable distance (1500 m) from the wind park, the immission level is for a considerable amount of time (at least 38% of night-time hours) higher than expected. At location B and at wind speeds of 2–4 m/s the actual sound level is up to 18 dB higher than expected, of which 3 dB are due to limitations of the calculation model, and 15 dB to the underestimate of wind speed at hub height. With these higher sound levels and the impulsive character of the sound more annoyance than predicted is to be expected.

Pedersen et al. [15] have investigated the annoyance around wind turbines in the south of Sweden. Their paper gives preliminary results, and definitive results have yet to be published (personal communication Pedersen). They found highly annoyed residents at (calculated) sound levels as low as 32.5–35 dB(A). This study shows that tall wind turbines may in fact be up to 18 dB noisier than the calculated values suggest. A further increase in annoyance may be expected because of the pulse-like character of the wind turbine noise, especially at high rotational speeds.

12. Conclusions

Sound immission measurements have been made at 400 m (location A) and 1500 m (location B) from the wind park Rhede with 17 tall (98 m hub height), variable speed wind turbines. It is usual in wind turbine noise assessment to calculate immission sound levels assuming wind speeds based on wind speeds v_{10} at reference height (10 m) and a logarithmic wind profile. This study shows that the sound immission level may, at the same wind speed v_{10} at 10 m height, be significantly higher (up to 18 dB) during night-time than in the daytime. Another, 'stable' wind profile predicts a wind speed v_h at hub height 1.8 times higher than expected and agrees excellently with the average measured night-time sound immission levels. Wind speed at hub height may still be higher; at low wind speeds v_{10} up to 4 m/s, the wind speed v_h at night is up to 2.6 times higher than expected.

Thus, the logarithmic wind profile, depending only on surface roughness and not on atmospheric stability, is not a good predictor for wind profiles at night. Especially for tall wind turbines, estimates of the wind regime at hub height based on the wind speed distribution at 10 m, will lead to an underestimate of the immission sound level at night: at low wind speeds ($v_{10} \leq 4 \text{ m/s}$) the actual sound level will be higher than expected for a significant proportion of time. This is not only the case for a stable atmosphere, but also, to a lesser degree, for a neutral atmosphere.

The change in wind profile at night also results in lower ambient background levels than expected: at night the wind speed near the ground may be lower than expected from the speed at 10 m and a logarithmic wind profile, resulting in low levels of wind induced sound from vegetation. The contrast between wind turbine and ambient sound levels is therefore more pronounced at night.

Measured sound immission levels at 400 m from the nearest wind turbine almost perfectly match (average difference: 0.1 dB) sound levels calculated from measured emission levels near the turbines. From this it may be concluded that both the emission and immission levels could be determined accurately, even though the emission measurements were not quite in agreement with the recommended method. As both levels can be related through a propagation model, it may not be necessary to measure both; the immission measurements can be used to assess immission as well as emission sound levels.

There is, however, a growing discrepancy with distance; at distances of 1-2 km the calculated level may underestimate the measured level by 3 dB. This is most probably a consequence of the fact that the actual (night-time) atmospheric sound transmission is not adequately modelled in the sound transmission model.

At night the turbines cause a low pitched thumping sound superimposed on a broadband 'noisy' sound, the 'thumps' occurring at the rate at which blades pass a turbine tower. It appears that the characteristic, but usually small 'swishing' pulses that can be heard at the rate at which blades pass a turbine tower, coincide because turbines operate nearly synchronously. Two coinciding pulse trains thus give a 3 dB higher pulse level, three a 5 dB higher pulse level. The measured pulse levels and frequencies agree with values expected from nearly synchronous pulse trains generated by a small number of wind turbines.

The number and severity of noise complaints near the wind park are at least in part explained by the two main findings of this study: actual sound levels are considerably higher than predicted, and wind turbines can produce sound with an impulsive character.

The relatively high wind speeds at turbine hub height at night also have a distinct advantage; the electric power output is higher than predicted and benefits the operator of the wind turbine.

Summary

Wind turbines produce low frequency sounds, but it has not been shown this is a major factor contributing to annoyance. Sound from wind turbines involves several sound production mechanisms related to different interactions between the turbine blades and the air. Low frequency sound is predominantly the result of the displacement of air by a blade and of turbulence at the blade surface.

An important contribution to the low frequency part of the sound spectrum may be the result of the sudden variation in air flow the blade encounters when it passes the tower: the angle of attack of the incoming air suddenly deviates from the angle that is optimized for the mean flow.

This effect probably has not been considered important as the blade passing frequency is of the order of one hertz where human hearing is very insensitive. This argument however obscures a very relevant effect: the low blade passing frequency modulates well audible, higher frequency sounds and thus creates periodic sound. This effect is stronger at night because in a stable atmosphere there is a greater difference between rotor averaged and near-tower wind speed. Measurements have shown that more turbines can interact to further amplify this effect.

The effect is confirmed by residents near wind turbines who mention the same common observation: often late in the afternoon or in the evening the turbine sound changes to a more 'clapping' or 'beating' sound, the rhythm in agreement with the blade passing frequency. It is clear from the observations that this is associated to a change to a higher atmospheric stability. The increased annoyance has not been investigated as such, although there are indications from literature this effect is relevant. It is of increasing relevance as the effect is stronger for modern (that is: tall) wind turbines.

Introduction

Modern wind turbines have electric power outputs up to 2 MW (increasing now to 5 MW) and have turbine heights of 80 to 100 meters (increasing to 120 m). In the European Union, producing 74% of the wind power in the world, by the end of 2002 23 GW has been installed, and this should increase to the European target of 40 GW for 2010, but already a capacity of 90 GW has been forecasted for that year [1]. As a result of this growth an increasing number of people are living near (projected) wind parks and have reason to inquire and perhaps be worried about their environmental impact. Visual impact, intermittent reflections on the turbine blades as well as intermittent shadows (sun behind rotating blades), and sound are usually considered potentially negative impacts.

Wind turbines are also suspected to be a cause of low frequency noise, affecting people living nearby. This has been brought forward in the United Kingdom where opponents of wind parks state "current recommendations for noise evaluation near wind turbine sites completely exclude the measurement of low frequency sound" [2]. In a reaction the British Wind Energy Association denies this and accuses the other party "to misunderstand technical information, but be happy to use the material in inappropriate ways. One example of this is their persistent misuse of material on noise". [3].

Yet, a recent review for the British Department for Environment, Food and Rural Affairs states: "Infrasound exposure is ubiquitous in modern life (.....) common in urban environments, and as an emission from (.....) air movement machinery including wind turbines (.....). The effects of infrasound or low frequency noise are of particular concern because of its pervasiveness (.....) compared with other noise." [4]. Also, according to a project proposal from the Swedish Kungl Technical Highschool "there is a risk for low frequency sound from the large wind turbine farms that are planned both in Sweden and in other European countries" [5]. So, those who link wind turbines with low frequency sound are in expert company. But, does it affect nearby residents?

This paper explores the nature of (low frequency) wind turbine sound and explains why low frequencies may be relevant and not relevant at the same time, depending on perspective.

Sources of wind turbine sound

There is a wealth of information on the nature, cause and power of turbine sound. A review resulting from a research programme of the European Union is given by Wagner *et al* [6]. A concise overview of the three sound source mechanisms relevant to this paper will be given here, preceded by an introduction on wind aeroacoustics.

If an air flow is smooth around a (streamlined) body, it will generate little sound. For high speeds and/or over longer lengths the flow in the boundary layer (between body and main flow) becomes turbulent. As this leads to rapid velocity changes this will cause more sound with frequencies related to the rate of the velocity changes. A typical size for this turbulence is the boundary layer thickness.

As is the case for aircraft wings or propeller blades, a wind turbine blade is driven by lift generated by the air flow and performs best when lift is maximized and at the same time drag (flow resistance) is minimized. Both are determined by the angle of attack: the angle between the incoming flow and the chord (line between front and rear edge) of the blade. When the angle of attack increases from its optimal value the turbulent boundary layer grows in thickness and turbulence strength, decreasing power performance and increasing sound level. For an increasing angle of attack this eventually leads to stall: a dramatic reduction in lift. Also, the atmosphere itself is turbulent over a wide range of frequencies and sizes.

Atmospheric turbulence energy has a maximum at a frequency that depends on height and atmospheric stability; for wind turbine altitudes this frequency is of an order of magnitude of once per minute (≈ 0.01 Hz), and the associated eddy (whirl) 'diameter' is of the order of magnitude of a several hundreds of meters [7]. Eddy diameter and turbulence strength decrease at increasing frequency and vanish because of viscous friction when they have reached the size of a millimeter.

Turbulent flow is the dominant cause of (audible) sound for modern wind turbines. There are several mechanisms whereby the sound actually is produced.

1 When a blade moves through the air, the air on the forward edge is moved sideways moving back again at the rear edge. So for a periodically moving blade the air is periodically forced, leading to 'thickness noise'. Normally this will not lead to a significant sound production

However, when a blade passes in front of the turbine tower, it encounters a wind that is influenced by the tower. The wind is slowed down and is forced to move sideways around the tower. This means that quite suddenly the angle of attack changes and lift and drag change abruptly. The change in mechanical load will increase thickness sound at the rate of the blade passing frequency f_b (f_b is the turbine rotation frequency multiplied by the number of blades). As the movement is not purely sinusoidal, there are harmonics with frequencies k/f_b where k is a (small) integer. As f_b typically has a value of approximately 1 Hz and harmonics may occur up to 10 - 20 Hz, this sound is in the infrasound region. Another consequence is that high frequency sound will also increase abruptly because of increased turbulence due to the sub-optimal angle of attack, creating the typical swishes superimposed on the constant noisy sound of a wind turbine.

2. Because of atmospheric turbulence there is a random movement of air superimposed on the average wind speed. The contribution of atmospheric turbulence to wind turbine sound is named 'in-flow turbulence noise' and is broad band sound stretching over a wide frequency range.

For turbulent eddies larger in size than the blade this may be interpreted as a change in the direction and/or velocity of the incoming flow, equivalent to a deviation of the optimal angle of attack. This leads to the same phenomena as in 1., but changes will usually be less abrupt.

For turbulent eddies the size of the chord length and less, effects are local and do not occur coherently over the blade. When the blade cuts through the eddies, the movement normal to the wind surface is reduced or stopped, given rise to high accelerations and thus sound.

3. High frequency sound is due to several flow phenomena at the blade itself or in the turbulent wake behind a blade ('airfoil self-noise'). It increases when induced turbulence increases, e.g. because of higher speed or of irregularities (scratches, dirt, insects) on the blade surface. It is essentially broad band sound, but if the turbulence can lock into a fixed length (such as a slit or cut parallel to the trailing edge), a specific frequency can become prominent, resulting in tonal sound.

Sound originating from the generator or the transmission gear has decreased in level in the past decade and has now become irrelevant if considering annoyance for residents.

Measured wind turbine sound spectra

In the summer of 2002 wind turbine sound has been recorded in and near wind park Rhode on the German-Dutch border. The park has a straight row of ten ca. 300 m spaced turbines parallel to the border and a less regular, somewhat uneven spaced row of seven turbines appr. 400 m behind the first row. Each turbine is 100 m high (hub height) with a blade length of 35 m, and produces nominally 2 MW electricity. It proved that the sound level, determined by the rotation speed of the turbines, depended on atmospheric stability and was not well predicted at evening and night hours by the usual reference wind speed measured at 10 meter altitude [8].

In figure 1 1/3 octave band spectra of the recorded sound have been plotted. The sound was recorded on a TASCAM DA-1 DAT-recorder with a precision Sennheiser microphone. The sound was then sampled in 1-second intervals on a Larson Davis 2800 frequency analyzer. The frequency response of the measurement chain is within 3 dB for frequencies above 4 Hz. From 1 to 4 Hz the frequency response is not accurately known (this has never been a necessity in our work). The spectra were determined from recordings (appr. 5 minutes each) taken with the microphone just above a hard surface at ground level at 100 m from two different turbines (plotted levels are measured Leq minus 6 dB correction for coherent reflection against the surface), and from a recording 1.5 m above a paved terrace and 2 m in

front of the façade of a dwelling at 750 m distance from the nearest row of turbines (measured L_{eq} minus 3 dB correction for incoherent reflection at the façade).

In each part of figure 1 200 spectra (spaced 1 sec) as well as the energy averaged spectrum have been plotted. Also the correlation coefficient α between all unweighted 1/3 octave band levels and the overall A-weighted sound levels has been plotted for each 1/3 octave band frequency. It is clear from the spectra that most energy is found at lower frequencies. This does not imply it is relevant for hearing as human hearing however is relatively insensitive at low frequencies. Indeed, the correlations show that most audible energy near the turbines is contained in the 1/3 octave band levels with frequencies from 400 through 3150 Hz (where $\alpha > 0.4$). For the sound at the façade this is one octave lower (200 - 1600 Hz) because higher frequencies were better absorbed and now contribute less to the sound energy as they do near the turbines.

In figure 2 thirteen more detailed 1-second 1/3 octave band spectra have been plotted from the sound on the façade (see figure 1). Although the bandwidth should be taken smaller to detect the harmonics of the blade passing frequency $f_b = 1$ Hz, the first harmonic at 2 Hz is clearly visible. A more detailed spectrum from a single turbine is given by Betke *et al* [9].

In figure 3 the three average spectra from figure 1 have been repeated, and the median hearing threshold for otologically selected young adults (according to ISO 226 [10]) has been added as well as the hearing threshold for the best hearing 10% of this group (10 percentile) which is 7 to 8 dB below the median level. It is clear that the sound below appr. 20 Hz must be considered inaudible for even well hearing people, even when one stands close to the turbine. Sound levels above the low frequency range but below appr. 1000 Hz are dominant with respect to audibility.

From figure 3 it is clear that sound levels at 100 m from a turbine (the two upper spectra) and at a location 750 m away from the first row of turbines are of comparable level at infrasonic frequencies, in fact the level differs only 4 dB. Although at the larger distance the sound level of a single turbine decreases, this is counterbalanced by the fact that more turbines contribute. At higher frequencies the same is true, but at increasing distance more sound energy is lost because of absorption.

The spectra in figure 3 are divided in three regions. For frequencies below 10 Hz the sound is dominated by thickness noise associated with the blade passing frequency (and harmonics). Then, in the higher infrasound region and upwards, where the level falls less steeply, in-flow turbulence is the dominant sound producing mechanism. Gradually, at frequencies above 100 Hz, airfoil self-noise is becoming the most dominant source, declining only at high frequencies of several kHz.

Impulsiveness

Wind turbine sound is not usually considered to be impulsive, as it has a more or less constant level due to the essentially random nature of the sound production mechanisms. Although there are periodic audible swishes, these are no equal to 'real impulses' like hammering or gun shots.

However, in a stable atmosphere the periodic swishes are louder than in daytime and residents use words like clapping, beating or thumping to describe the character of the sound. In the case of the Rhede wind park, the beating can be heard clearly at distances of at least up to 1 km and at night one can use it to determine the rotational speed of the turbine. So perhaps wind turbines can produce impulsive sound, but only in specific atmospheric conditions: the atmosphere must be stable. To understand this we must understand the implications of a stable atmosphere with respect to wind, the matter driving wind turbines

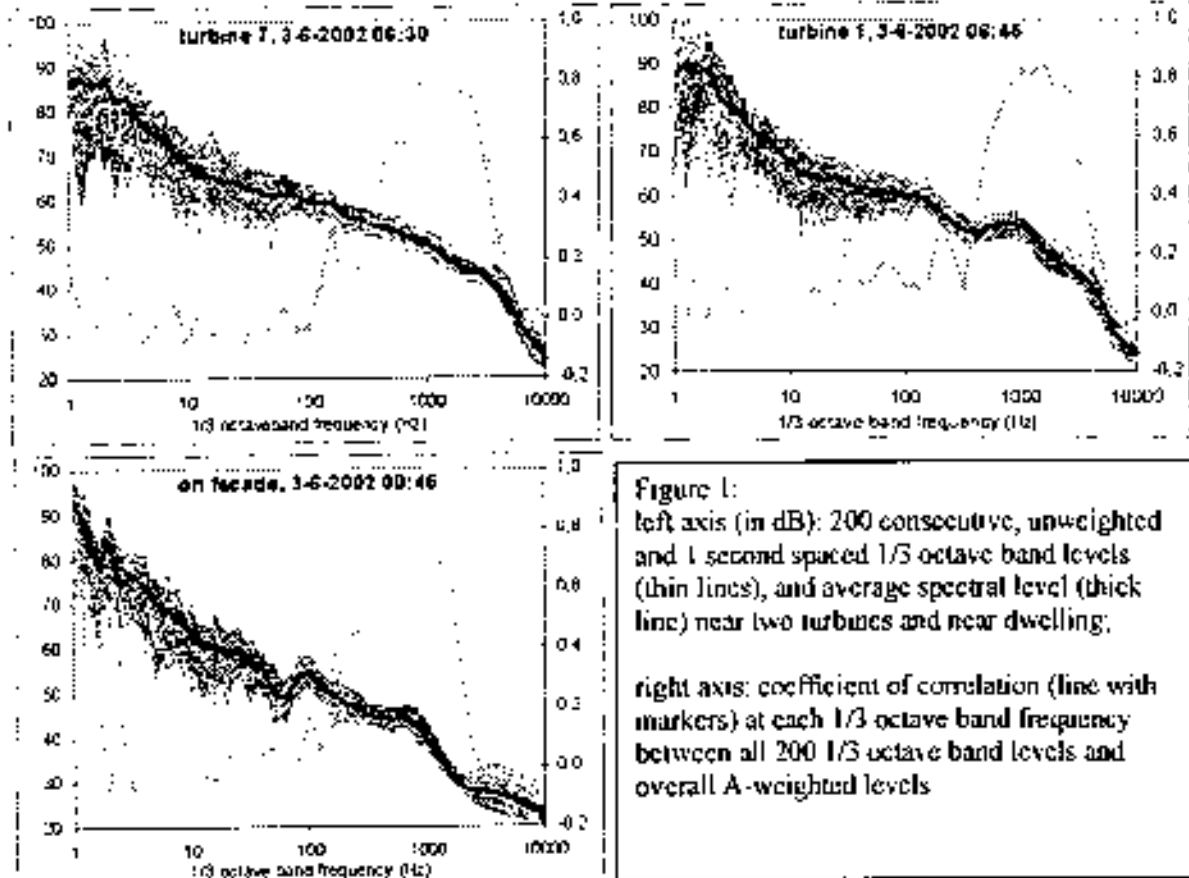

Figure 1:
 left axis (in dB): 200 consecutive, unweighted and 1 second spaced 1/3 octave band levels (thin lines), and average spectral level (thick line) near two turbines and near dwelling;
 right axis: coefficient of correlation (line with markers) at each 1/3 octave band frequency between all 200 1/3 octave band levels and overall A-weighted levels

Figure 2-
 13 unweighted, 1 second spaced 1/3 octave band levels near a turbine

Figure 3: regions in 1/3 octave band spectra near turbines (grey and thin black line) and dwelling (dotted line) with average spectrum slope in dB/decade, and 10 and 50 percentile hearing threshold level for young adults

The wind speed v_h at height h in the atmosphere can be written as:

$$v_h = v_{ref} (h/h_{ref})^m \quad (1)$$

where v_{ref} is the wind speed at a reference height h_{ref} (usually 10 m). The exponent m depends upon atmospheric stability. For a neutral atmosphere, occurring under heavy clouding and/or in strong winds, air buoyancy dominates thermal effects and m has a value of appr. 0.2. In an unstable atmosphere, as is usual in daytime (if not neutral), m has a value of appr. 0.1. In a stable atmosphere m should theoretically reach values up to a maximum of $1/2 \sqrt{2}$, describing a parabolic wind profile corresponding to laminar flow. Our Rhede measurements yielded values of m up to 0.6 [8]. A sample from data from the Royal Dutch Meteorological Institute KNMI [11] shows that indeed this theoretical maximum can be reached: in ten out of twelve midnight half hours (averages over 0:00 – 0:30 GMT) of each first night of the month there was a temperature inversion in the lower 120 m, indicating atmospheric stability. Of these in six cases the temperature increased with more than 1 °C from 10 to 120 m height and the exponent m (calculated from (1): $m = \log(v_{20}/v_{10})/\log(2)$) was 0.43, 0.44, 0.55, 0.58, 0.67 and 0.72 (we expect to do a more thorough analysis on more data to obtain statistically relevant long-term results).

In the following text we will use a value $m = 0.1$ for an unstable atmosphere and $m = 0.6$ for a stable atmosphere. These values will be used for altitudes between 10 and 120 m. It is probable that the wind profile above 120 m will not follow formula (1), as eventually a more or less constant wind speed (the geostrophic wind) will be attained, perhaps, in a stable atmosphere, after a decrease when the top of a 'low level jet' at about 100 m height has been reached. Because of this, the optimal height for a windturbine from an energetic point of view will probably be about 100 m.

Effects depend on wind turbine properties (such as speed, diameter and height). We will use typical dimensions of a modern 1.5-2 MW wind turbine, hub height 80 m, rotor diameter 70 m and rotational speed increasing with wind speed to a maximum value of 20 rpm.

Now there are two reasons why the periodic swishes acquire a more impulsive character in a stable atmosphere relative to an unstable or neutral atmosphere.

1- Rotational speed will be determined by a rotor averaged wind speed, but the difference in wind speed between the upper and lower part of the rotor increases. Suppose the wind speed at hub height is $v_{80} = 8$ m/s. Then in daytime ($m \approx 0.1$) the wind speed at the lowest point of the rotor would be $v_{45} = 7.6$ m/s, at the highest point $v_{115} = 8.3$ m. The difference in wind speed over the rotor of 0.35 m/s causes a change in angle of attack of only 0.25° (both plus or minus relative to average value). A very slight vertical tilt of the rotor can offset this. In nighttime ($m = 0.6$) however, at the same wind speed at hub height, v_{45} is 5.7 m/s and v_{115} 9.9 m/s, so the difference in wind speed over the rotor and the change in angle of attack are now 6 times as large: 2.1 m/s and 1.5°, respectively. As a consequence there will be more airfoil self-noise.

A further effect is that there is a greater mismatch between optimum and actual angle of attack when the blade passes the mast (where there was already a mismatch due to the tower), causing higher blade loading and more turbulence. This effect is readily audible when night falls: the blades start clapping or beating at the blade passing frequency. The effect is stronger when stability increases, and also when wind speed at hub height increases up to the point where friction turbulence overrides stability and the atmosphere becomes neutral.

2- As was shown earlier [8], in a stable atmosphere wind turbines can run almost synchronously because the relative absence of turbulence leads to less random motion

superimposed on the constant (average) wind speed at each turbine. Turbines in a wind park therefore experience a wind that is more constant over greater distances. As a result they tend to react the same, that is: their turbine speeds are more nearly equal. This is confirmed by long term measurements by Nanahara *et al* who analysed coherence of wind speeds at locations at increasing distances in two coastal areas [12]. At night hours wind speeds at different locations were found to change more coherently than they did at daytime [13]. The difference between night and day hours was not very strong, probably because just time of day is a helpful, but not sufficient indicator for stability, especially not near sea and over all day lengths in an entire year.

Because of the *near-synchronicity* of several turbines, sometimes two are in phase and the blade passing pulses coincide, and then go out of phase again. The same can happen for three and perhaps more turbines. Exact synchronicity would not give the same effect, because it is improbable that an observer would hear these pulses at the same time. Because of near-synchronicity however, an observer will hear coinciding pulses for part of the time. Synchronicity here refers to the sound pulses of the different turbines at the location of the observer: pulses synchronize when they arrive simultaneously. This does not imply that the rotors are in phase: in that case the pulses would not arrive simultaneously unless the turbines would be at a distance to the observer equal to the distance sound propagates in one pulse repetition time or a multiple.

Both effects, the wind speed gradient and the near-synchronicity, increase the level of the sound heard when the blades pass the tower. The extra blade loading itself is not audible because of the high hearing threshold at the very low blade passing frequency. But the effect of added induced turbulence increases the levels at frequencies that already were dominating the best audible part of the sound, that is, at 750 m distance, at 200 – 1600 Hz (= range with high correlation in figure 1). When the pulses at the Rhode wind park synchronize, the level of the 800 Hz 1/3 octave band (best correlated to audibility: see façade spectrum in figure 1) increases with 10 dB, whereas the total A-weighted level increases with 5 dB. In general the height of the pulse will depend on the change in angle of attack and the distances of the wind turbines relative to the observer: the beat due to several turbines will reach higher pulse levels when more turbines are at approximately equal distances and contribute equal immission levels. The clapping or beating is thus at well-audible frequencies and has a repetition rate equal to the blade passing frequency.

Window rattling

Although infrasound levels from large turbines at frequencies below 20 Hz are too low to be audible, they may cause structural elements of buildings to vibrate. The vibrations may produce higher frequency, audible sound.

Windows are usually the most sensitive elements as they move relatively easy because of the low mass per area. Perceptible vibrations of windows may occur at frequencies from 1 to 10 Hz when the incoming 1/3 octave band sound pressure level is at least appr. 52 dB [14]; at higher or lower frequencies a higher level is needed to produce perceptible vibrations. As can be seen in figures 1 – 3 sound pressure levels above 60 dB at frequencies below 10 Hz occur close to a turbine as well as at 750 m distance and further.

A window vibrating at the impinging frequency transmits this frequency to the indoor air. If this does not coincide with a room resonance, the sound will not be louder than outdoors. For rooms in dwellings with a greatest dimension of 10 m, resonance frequencies are higher than appr. 15 Hz and thus cannot coincide with relevant harmonics of f_b , the blade passing frequency.

However, a window pane itself may have a resonant frequency of, e.g., 40 Hz and a frequency of 10 Hz then may sustain a window pane resonance, thus transforming inaudible infrasound to audible higher frequencies. Also, a loosely fitted window may move to and fro and being stopped by the window frame vibrates at higher frequencies radiated into the room.

Conclusion

Infrasonic harmonics of the blade passing frequency from modern, tall wind turbines must be considered inaudible. Low frequency in-flow turbulence sound may be audible, but wind turbine sound is loudest at medium to high frequencies. This readily audible sound is caused by atmospheric and induced turbulence at the blade surface. The level of this medium/high frequency turbulent sound varies at the rate of the blade passing frequency, which causes the typical swishing sound of a modern wind turbine.

When the atmosphere becomes more stable, which is usual at night when there is a partial clear sky and a light to moderate wind (at ground level), there is an important change in wind profile affecting the performance of a modern, tall wind turbine. The airflow around the blade then changes to less than optimal, resulting in added induced turbulence. This effect is strongest when the blades pass the tower, causing short lasting, higher sound levels at the rate of the blade passing frequency. In a wind park these pulses can synchronize, leading to still higher pulse levels for an observer outside the park. The resulting repetitive pulses change the character of the wind park sound and must be expected to cause added annoyance.

SUMMARY

Sound from wind turbines involves a number of sound production mechanisms related to different interactions between the turbine blades and the air. An important contribution to the low frequency part of the sound spectrum is due to the sudden variation in air flow which the blade encounters when it passes the tower: the angle of attack of the incoming air suddenly deviates from the angle that is optimized for the mean flow. Hitherto, low-frequency sound from wind turbines has not been shown to be a major factor contributing to annoyance. This seems reasonable as the blade passing frequency is of the order of one hertz where the human auditory system is relatively insensitive. This argument, however, obscures a very relevant effect: the blade passing frequency modulates well audible, higher-frequency sounds and thus creates periodic sounds: *blade swish*. This effect is stronger at night because in a stable atmosphere there is a greater difference between rotor averaged and near-tower wind speed. Measurements have shown that additional turbines can interact to further amplify this effect. Theoretically the resulting fluctuations in sound level will be clearly perceptible to human hearing. This is confirmed by residents near wind turbines with the same common observation: often late in the afternoon or in the evening the turbine sound acquires a distinct ‘beating’ character, the rhythm of which is in agreement with the blade passing frequency. It is clear from the observations that this is associated to a change towards a higher atmospheric stability. The effect of stronger fluctuations on annoyance has not been investigated as such, although it is highly relevant because a) the effect is stronger for modern (that is: tall) wind turbines, and b) more people in Europe will be living close to these wind turbines as a result of the growth of wind energy projects.

1. INTRODUCTION

Modern onshore wind turbines have peak electric power outputs of around 2 Mw and tower heights of 80 to 100 meters. In 2003, 75% of the global wind power peak electric output of 40 Gw was installed in the European Union. The original European target for 2010 was 40 Gw, but the European Wind Energy Association have already set a new target for 2010 of 75 Gw, of which 10 Gw is projected off-shore, while others have forecast a peak output of 120 Gw for that year [1]. Whether this growth will actually occur is uncertain, with the proportional increase of wind energy in total electric power the difficulties and costs of integrating large scale windpower with respect to grid capacity and stability, reserve capacity and CO₂ emission reductions are becoming more prominent (see, e.g., [31, 32]). However, further expansion of wind energy is to be expected, and as a result of this (predominantly on-shore) growth an increasing number of people may face the prospect of living near wind farms, and have reason to inquire, and perhaps be worried about their environmen-

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

tal impact. Visual intrusion, intermittent reflections on the turbine blades, as well as intermittent shadows (caused when the rotating blades pass between the viewer and the sun), and sound, are usually considered potentially negative impacts.

Atmospheric stability has hitherto not been considered with respect to wind turbine sound. However, at the heights that are reached by modern, tall wind turbines the effect has become increasingly important, from an energetic as well as acoustical point of view.

In an earlier paper [2] it has been shown that in a stable atmosphere the sound level due to wind turbines is higher than is expected from sound production based on simple logarithmic extrapolation from reference wind speeds. The present paper explores the effect of atmospheric stability on the periodic level changes known as 'blade swish'. In the next two sections three possibly relevant effects of a change in atmospheric stability are identified and investigated from a theoretical point of view. All effects result in a higher level of blade swish. Then, in section 4, we will turn to measurement results and show that measured results can be explained by these predicted effects. Finally, in section 5, the results are put in the context of human perception. It can now be understood why in a stable atmosphere (but not in an unstable atmosphere) wind turbine sound is perceived as a fluctuating sound.

2. SOURCES OF WIND TURBINE SOUND

There are many publications on the nature and power of turbine sound. See, e.g., the studies by Lawson [3] and Grosveld [4], and the reviews by Hubbard and Shepherd [5] and Wagner *et al.* [6]. A short introduction on wind aerodynamics will be given to elucidate the most important sound producing mechanisms.

If an air flow is smooth around a (streamlined) body, it will generate very little sound. For high speeds and/or over longer lengths the flow in the boundary layer between the body and the main flow becomes turbulent. The rapid turbulent velocity changes at the surface cause sound with frequencies related to the rate of the velocity changes. The turbulent boundary layer at the downstream end of an airfoil produces *trailing edge sound*, which is the dominant audible sound from modern turbines.

As is the case for aircraft wings, the air flow around a wind turbine blade generates lift. An air foil performs best when lift is maximised and drag (flow resistance) is minimised. Both are determined by the angle of attack: the angle (α) between the incoming flow and the blade chord (line between front and rear edge; see figure 1). When the angle of attack increases from its optimal value the turbulent boundary layer on the suction (low pressure) side grows in thickness, thereby decreasing power performance and increasing sound level. For high angles of attack this eventually leads to stall, that is: a dramatic reduction in lift.

Apart from this turbulence inherent to an airfoil, the atmosphere itself is turbulent over a wide range of frequencies and sizes. Turbulence can be defined as changes over time and space in wind velocity and direction, resulting in velocity components normal to the airfoil varying with the turbulence frequency causing *in-flow turbulent sound*. Atmospheric turbulence energy has a maximum at a frequency that depends on height and on atmospheric stability. For wind turbine altitudes this peak frequency is of an order of magnitude of once per minute (0.017 Hz). The associated eddy (whirl) scale is of the order of magnitude of several hundreds of meters [7] in an unstable atmosphere, less in a stable atmosphere. Eddy size and turbulence strength decrease at higher frequency, and vanish due to viscous friction when they have reached a size of approximately one millimetre.

Figure 1 Flow impinging on a turbine blade.

A third sound producing mechanism is the response of the blade to the change in lift when it passes the tower. The wind is slowed down by the tower which changes the angle of attack. The resulting sideways movement of the blade causes *thickness sound* at the blade passing frequency and its harmonics.

A more thorough review of these three sound production mechanisms is given in Appendix 1, where frequency ranges and sound levels are quantified in so far as relevant for the present paper. A modern wind turbine sound spectrum can now be divided in (overlapping) regions corresponding to these three mechanisms:

1. Infrasonic frequency ($f < 30$ Hz): the *thickness sound* is tonal, the spectrum containing peaks at the blade passing frequency f_B and its harmonics
2. Low frequency, *in-flow turbulent sound* is broad-band noise with a maximum level at approximately 10 Hz and a slope of 3–6 dB per octave.
3. High frequency: *trailing edge (TE) sound* is noise with a maximum level at 500–1000 Hz for the central octave band, decreasing by 11 dB for neighbouring octave bands and more for further octave bands.

Sound originating from the generator or the transmission gear has decreased in level in the past decades and has become irrelevant when considering annoyance for residents. As thickness sound is not relevant for direct perception, turbulent flow is the dominant cause of (audible) sound for modern wind turbines. It is broad-band noise with no tonal components and only a little variation, known as blade swish. Blade swish is sound due to the regular increase in trailing edge sound whenever a blade passes the tower. Trailing edge (TE) sound level is proportional to $50 \log M$ (see equation A4 in appendix), where M is the Mach number of the air impinging on the blade. TE sound level therefore increases steeply with blade speed and is highest at the high velocity blade tips. Swish thus originates predominantly at the tips.

Sound from downwind rotors, i.e. with the rotor downwind from the tower, was considered problematic as it was perceived as a pulsating sound (see appendix). For modern upwind rotors this variation in sound level is weaker. It is not thought to be relevant for annoyance and considered to become less pronounced with increasing distance due to loss of the effect of directivity, due to relatively high absorption at swish frequencies, and because of the increased masking effect of background noise [8]. However, several effects that increase the level of the swishing sound and are related to increasing atmospheric stability have not been taken into account as yet. Possible effects will be considered before we turn to measurement results.

3. EFFECT OF ATMOSPHERIC STABILITY ON WIND TURBINE SOUND

The wind speed v_z at height h in the atmosphere can be written as:

$$v_z = v_{ref} \left(\frac{h}{h_{ref}} \right)^{\alpha} \quad (1)$$

where reference height h_{ref} is usually 10 m [2, 7]. The relation is suitable where h is at least several times the roughness length. At high altitudes the wind profile will not follow (1), as eventually a more or less constant wind speed (the geostrophic wind) will be attained. At higher altitudes in a stable atmosphere there may be a decrease in wind speed when a nocturnal 'jet' develops. The maximum in this jet is caused by a transfer of kinetic energy from the near ground air that decouples from higher air masses as large, thermally induced eddies vanish because of ground cooling. In fact, reversal of the usual near-ground diurnal pattern of low wind speeds at night and higher wind speeds in daytime is a common phenomenon at higher altitudes over land in clear nights [9, 10, 11]. Over large bodies of water the phenomenon may be seasonal as stability occurs more often when the water is relatively cold (winter, spring). This may also be accompanied by a maximum in wind velocity at a higher altitude [12].

In a neutral atmosphere the wind profile can also be modelled with the well known logarithmic or adiabatic profile, where relative wind speed v_z/v_{ref} depends on height and surface roughness. This model is widely (and, as yet, only) used in relation to wind turbine sound (see, e.g., [8] or [14]). With regard to wind power

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

more attention is being paid to stability effects and thus to other wind profile models [see, e.g., 10, 11, 12, 15, 16]. Accurate wind speed profiles can be calculated with a diabatic wind speed model where stability corrections are added to the diabatic profile (see, e.g., [9] or [13]).

Equation (1) has no theoretical basis, but often provides a good fit to the vertical wind profile, especially when the atmosphere is non-neutral. In flat terrain the stability exponent m has a value of 0.1 and more. In daytime or in windy nights ($0.1 < m < 0.2$) equation (1) does not deviate much from the logarithmic wind profile, for altitudes up to 100 m and low vegetation (roughness length < 10 cm), wind velocities calculated with equation 1 agree within 20% with the logarithmic wind profile.

For a neutral atmosphere, occurring under heavy clouding and/or in strong winds, m has a value of approx. 0.2. In an unstable atmosphere (occurring in daytime) thermal effects caused by ground heating are dominant. Then m has a lower value, down to approx. 0.1. In a stable atmosphere vertical movements are damped because of ground cooling. One would then eventually expect a parabolic wind profile, as is found in laminar flow, corresponding to a value of m of $0.7 = \sqrt{3/2}$. Our measurements near the Rhede wind farm (53° 6' 2" latitude, 7° 12.6' longitude) at the German-Dutch border [2] yielded values of m up to 0.6. A sample average over 0:00-0:30 GMT of each first night of the month in 1997) from data from a 200 m high tower in flat agricultural land [27] shows that the theoretical value is indeed reached: in ten out of the twelve samples there was a temperature inversion in the lower 120 m, indicating atmospheric stability. In six samples the temperature increased with more than 1 °C from 10 to 120 m height and the exponent m (calculated from (1): $m = \log(v_{10}/v_{120}) / \log(8)$) was 0.45, 0.44, 0.55, 0.58, 0.67 and 0.72. Comparable values have been estimated in the US Midwest [15] and at a Spanish plateau [16]. In the following text we will use a value $m = 0.15$ for a daytime atmosphere (unstable + neutral), $m = 0.4$ for a stable, and $m = 0.65$ for a very stable atmosphere. These values will be used for altitudes between 10 and 120 m.

The magnitude of the effects of increasing stability depends on wind turbine properties such as speed, diameter and height. We will use the dimensions of the wind turbines in the Rhede wind farm, that are typical for a modern 1.5-2 MW wind turbine: hub height 100 m, blade length 35 m and rotational speed increasing with wind speed up to a maximum value of $\Omega R = 73$ m/s (at 20 rpm).

There are now three factors influencing blade swish level when the atmosphere becomes more stable: a) the higher wind speed gradient, b) the higher wind direction gradient, and c) the relative absence of large scale turbulence.

a) *Wind speed gradient.* Rotational speed is determined by a rotor averaged wind speed. With increasing atmospheric stability the difference in wind speed between the upper and lower part of the rotor increases. Suppose that the wind speed at hub height is $v_{100} = 14$ m/s, corresponding to $v_{10} = 9.8$ m/s in a neutral atmosphere in flat open grass land (roughness length 4 cm). Then in daytime ($m = 0.15$) the wind speed at the lowest point of the rotor would be $v_{25} = 13.1$ m/s, at the highest point $v_{175} = 14.6$ m/s. As the blade angle does not change with rotation angle, the difference between the low tip and hub height wind speeds causes a change in angle of attack on the blade of $\Delta\alpha = 0.8^\circ$ at 20 rpm (see appendix, equation A7). Between the high tip and hub height the change is smaller, 0.5° . In night-time ($m = 0.4$), at the same wind speed at hub height, v_{100} is 11.8 m/s causing a change in angle of attack at the lower tip relative to hub height of 1.8° (at the high tip: $v_{175} = 15.8$ m/s, $\Delta\alpha = 1.5^\circ$). When the atmosphere is very stable ($m = 0.65$), wind speed $v_{25} = 10.5$ m/s and the angle of attack on the low altitude tip deviates 3.9° from the angle at hub height (at the high tip: $v_{175} = 17.0$ m/s, $\Delta\alpha = 2.5^\circ$).

In fact when the lower tip passes the tower there is a greater mismatch between optimum and actual angle of attack because there was already a change in angle of attack related to the wind velocity deficit in front of the tower. For a daytime atmosphere and with respect to the situation at hub height, the change in α associated to a blade swish level of $L \pm 0.5$ dB is estimated as $2.1 \pm 0.4^\circ$ (see appendix, section C), part of which (0.8°) is due to the wind profile and

the rest to the tower. The increase in α due to the stability related wind profile change must be added to this daytime change in α . Thus, relative to the daytime (unstable to neutral) atmosphere, the change in angle of attack when the lower tip passes the mast increases with 1.0° in a stable atmosphere, and with 2.1° in a very stable atmosphere. The associated change in trailing edge (TE) sound level, as calculated from equation A6 in the appendix, is 3.1 ± 0.7 dB for a stable and 5.0 ± 0.8 dB for a very stable atmosphere (compared to 1 ± 0.5 dB in daytime). The corresponding total A-weighted sound level will be somewhat less as trailing edge sound is not the only sound source (but it is the dominant source; see section 4C).

At the high tip the change in angle of attack is smaller than for the low tip as there is no (small) tower induced change to add to the wind gradient dependent change. The change in angle of attack at the high tip in a very stable atmosphere (2.5°) is comparable to the change at the low tip in daytime, and this change is more gradual than for the low tip.

Thus we find that, for $v_{10m} = 14$ m/s, the 1-2 dB daytime blade swish level increases to approx. 5 dB in a very stable atmosphere. The effect is stronger when wind speed increases up to the point where fraction turbulence overrides stability and the atmosphere becomes neutral. The increase in trailing edge sound level will be accompanied by a lower peak frequency (see appendix, equation A2). For $\alpha = 5^\circ$ the shift is one octave.

- b. *Wind direction gradient.* In a stable atmosphere air masses at different altitudes are only coupled by small scale turbulence and are therefore relatively independent. Apart from a higher velocity gradient a higher wind direction gradient is also possible, and with increasing height the wind direction may change significantly. This wind direction shear will change the angle of attack with height. Assuming the wind at hub height to be normal to the rotor, the angle of attack will decrease below and increase above hub height (or vice versa). This effect, however, is small; if we suppose a change in wind direction of 20° over the rotor height at a wind velocity of 10 m/s, the change in angle of attack between extreme tip positions at 20 rpm is only 0.25° , which is negligible relative to the wind velocity shear.
- c. *Less turbulence.* As was shown in an earlier study [2], in areas near a wind farm an increase in blade swish pulse height (The term 'pulse' is used to indicate the upward variation in sound level.) can be explained by the synchronization of two or three pulse trains coming from the two or three closest turbines. In a stable atmosphere wind turbines can run almost synchronously because the absence of large scale turbulence leads to less variation superimposed on the constant (average) wind speed at each turbine. In unstable conditions the average wind speed at both turbines will be equal, but instantaneous local wind speeds will differ because of the presence of large, turbulent eddies at the scale of the inter-turbine distance. In a stable atmosphere the turbulence scale decreases with a factor up to 10, relative to the neutral atmosphere and even more relative to an unstable atmosphere [17]. In stable conditions turbines in a wind farm therefore experience a more similar wind and as a consequence their instantaneous turbine speeds are more nearly equal. This is confirmed by long term measurements by Nishihara *et al.* [18] who analysed coherence of wind speeds between different locations in two coastal areas. At night wind speeds at different locations were found to change more coherently than they did at daytime [19]. The difference between night and day was not very strong, probably because time of day on its own is not a sufficient indicator for stability. The decay of coherence was however strongly correlated with turbulence intensity, which in turn is closely correlated to stability. (In a coastal location atmospheric stability also depends on wind direction as landwards stability is a diurnal, but seawards a seasonal phenomenon. Also, a fixed duration for all nights in a year does not coincide with the time that the surface cools (between sundown and sunrise), which is a prerequisite for stability.)

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

Near the Rhode wind farm we found that, because of the near-synchronicity of several turbines, sometimes two or three were in phase and the blade passing pulses coincided, and then went out of phase again [2]. This would lead to a doubling (+3 dB) or tripling (+5 dB) of pulse height H in a (very) stable atmosphere individual swish pulse heights are 3–5 dB (see section 3a above). Synchronicity at the Rhode wind farm or similar configurations would thus lead to pulse heights of 6–10 dB.

Synchronicity here refers to the sound pulses from the different turbines as observed at the location of the observer. So, pulses synchronise when they arrive simultaneously. This is determined by differences in phase (rotor position) between turbines and in propagation distances of the sound from the turbines. Phase differences between turbine rotors occur because turbines are not connected and because of differences in actual performance. The place where synchronicity is observed will change when the phase difference between turbines changes. With exact synchronicity there would be a fixed interference pattern, with synchronicity at fixed spots. Because of near-synchronicity however, synchronicity will change over time and place and an observer will hear coinciding pulses for part of the time only.

A second effect of the decrease in turbulence strength is that in-flow turbulent sound level also decreases. The resulting decrease in broad band sound level lowers the minimum in the temporal variations, thereby increasing modulation depth.

We conclude that the higher wind speed gradient and (near-) synchronicity increase blade swish levels at some distance from a wind farm. The higher infrasound level due to extra blade loading is not perceptible because of the high hearing threshold at the very low blade passing frequency. However, the effect of added boundary layer turbulence on the blade increases the levels at the higher frequencies that already were dominating the most audible part of the sound. Near a wind farm the variation in sound level will depend on the distances of the wind turbines relative to the observer: the level increase due to several turbines will reach higher levels when more turbines are at approximately equal distances and thus contribute equal immersion levels. The increase in level variation, or beating, is thus at well-audible frequencies and has a repetition rate equal to the blade passing frequency.

Thus, theoretically it can be concluded that in stable conditions (low ambient sound level, high turbine sound power and higher modulation or swish level) wind turbine sound can be heard at greater distances and is of lower frequency due to absorption and the frequency shift of swish sound. It is thus a louder and more low-frequency 'thumping' sound and less the swishing sound that observed close to a daytime wind turbine.

4. MEASUREMENT RESULTS

4.1. Locations

In the summers of 2002 and 2004 wind turbine sounds have been recorded in and near the Rhode wind farm on the German-Dutch border. The farm (figure 2) has a straight south to north row of ten turbines at approximately 300 m intervals, running parallel to the border, and seven less regularly spaced turbines east of the straight row. Each turbine is 98 m to the hub height, and has a blade length of 35 m, and produces nominally 1.8 MW electric power.

The measurement location at dwelling R is west of the turbines, 625 m from the nearest turbine. The microphone position was at 4 m height and close to the house, but with no reflections except from the ground. The measurement location at dwelling P, 870 m south of R, was 1.5 m above a gravel terrace in front of the façade of the dwelling at 750 m distance from the nearest turbine. The entire area is quiet, flat, agricultural land with some trees close to the dwellings. There is little traffic and there are no significant permanent human sound sources.

A third dwelling Z is in Boazum in the northern part of the Netherlands, 380 m west of a single, two-speed turbine (45 m hub height, 23 m blade length, 2026 rpm). The area is again quiet, flat and agricultural. The immersion measurement point is at 1.5 m height above gravel near the dwelling. This measurement site is included here to show that the influence of stability on blade swish levels occurs also with

Figure 2 Turbines (grey circles) in and measurement locations (A,B,Z) near the three wind farms; solid lines are roads.

Table 1. Overview of measurement locations and times and of turbine speed and wind

Location	Measurement		Turbine speed (rpm)	Wind speed (m/s)		Wind direction ($^{\circ}$ north)
	Date	Time		v_{10}	v_{hub}	
Dwelling P	June 1, 2002	20:45	20	5	14	100
Turbine 7	June 3, 2002	06:30	19	5	35	100
Turbine 1	June 3, 2002	06:45	19	5	35	100
Dwelling R	Sep. 9, 2004	23:07	18	4	14	80
Turbine 16						
Dwelling Z	Oct. 18, 2003	08:43	36	3	6	60

smaller, single turbines. At all locations near dwellings the microphone was fitted in a 9 cm diameter foam wind screen.

Table 1 gives an overview of measurement (start) times and dates of observed turbine speeds and of wind speed and direction, for situations for which results will be given below. The wind speed at hub height v_{hub} has been determined from turbine rotation speed N or sound power level $L_{w,eq}$ ([2]), the relation $v_{hub} = N$ follows from ref. 3 and 11 in ([1]). The wind speed v_{10} at 10 m height was continuously measured at or near location A, except for location Z, where data from several meteorological stations were used showing that the wind was similar and nearly constant in the entire northern part of the Netherlands. In all cases there were no significant variations in wind speed at the time of measurement. Wind speed at the microphone was lower than v_{10} because of the low microphone height and shelter provided by trees nearby. Wind direction is given in degrees relative to north and clockwise 190 $^{\circ}$ is east). The spectra near a turbine were measured with the microphone just above a hard surface at ground level 100 m downwind of a turbine in compliance with IEC 61400-114) as much as possible (non-compliance did not lead to differences in result [2]; for reasons of non-compliance, see [34]). The levels plotted are emission levels: measured L_{eq} minus 6 dB correction for coherent reflection against the hard surface ([16]). The plotted levels near the dwellings are also emission levels: measured L_{eq} minus 3 dB correction for incoherent reflection at the facade for dwelling P, or measured L_{eq} without any correction for dwellings R and Z.

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

At dwelling P at the time of measurement the beat in the turbine sound was very pronounced. In the other measurements (dwellings R and Z) the beating was not as loud. The measurements near turbine 16 and dwelling R at 23:07 on September 9 were performed simultaneously.

4.2. Frequency response of instruments

For the Rhode measurements sound was recorded on a TASCAM DA-1 DAT-recorder with a precision 1 in Sennheiser MKH 20 P48 microphone. The sound was then sampled in 1-second intervals on a Larson Davis 2800 frequency analyser. From 1 to 10 000 Hz the frequency response of the DAT-recorder and LD2800 analyser have been determined with a pure tone electrical signal as input. The LD2800 response is flat (± 1 dB) for all frequencies. The DAT-recorder is a first order high pass filter with a corner frequency of 2 Hz. The frequency response of the microphone was of most influence and has been determined relative to a B&K 93 in microphone type 4189 with a known frequency response [20]. Equivalent spectral sound levels with both microphones in the same sound field (approx. 10 cm mutual distance) were compared. For frequencies of 2 Hz and above the entire measurement chain is within 3 dB equivalent to a series of two high pass filters with corner frequencies of $f_1 = 4$ Hz and $f_2 = 9$ Hz, or a transfer function equal to $-20 \log |1 + (f_1/f)^2| - 20 \log |1 + (f_2/f)^2|$. For frequencies below 2 Hz this leads to high signal reductions (< -40 dB) and consequentially low signal to (system) noise ratios. Therefore values at frequencies < 2 Hz are not presented.

For the Bruel measurements sound was recorded on a Sharp MD-MT99 minidisc recorder with a 1/2 in Sennheiser MEb2 microphone. The frequency response of this measurement chain is not known, but is assumed to be flat in the usual audio frequency range. Simultaneous measurements of the broad band A-weighted sound level were done with a precision (type 1) sound level meter. Absolute precision is not required here as the minidisc recorded spectra are only used to demonstrate relative spectral levels. Because of the ATRAC time coding of a signal, a minidisc recording does not accurately follow a level change in a time interval < 11.6 ms. This is insignificant in the present case as the 'fast' response time of a sound level meter is much slower (125 ms).

4.3. Measured Emission and Immission Spectra

Recordings were made at evening, night or early morning. On June 3, 2002, sound was recorded at dwelling P at around midnight and early in the morning near two turbines (numbers 1 and 7). At P at these times a distinct beat was audible in the wind turbine sound. In figure 3, 1/3 octave band spectra of the recorded sound at P and at both turbines have been plotted. In each figure A, B and C, 200 sound pressure spectra sampled in one-second intervals, as well as the energy averaged spectrum of the 200 samples have been plotted. The standard deviation of 1/3 octave band levels is typically 7 dB at very low frequencies, decreasing to approx. 1 dB at 1 kHz. The correlation coefficient ρ between all unweighted 1/3 octave band levels and the overall A-weighted sound level has also been plotted for each 1/3 octave band frequency.

For frequencies below approximately 10 Hz the sound is dominated by the thickness sound associated with the blade passing frequency and harmonics. In the rest of the infrasound region and upwards, in-flow turbulence is the dominant sound producing mechanism. Gradually, at frequencies above 100 Hz, trailing edge sound becomes the most dominant source, declining at high frequencies of one to several kHz. Trailing edge sound is more pronounced at turbine 1 (T1) compared to turbine 7 (T7), causing a hump near 1000 Hz in the T1 spectra. At very high frequencies (> 2 kHz) sometimes higher spectral levels occur due to birds.

It is clear from the spectra that most energy is found at lower frequencies. However, most of this sound is not perceptible. To assess the infrasound level relevant to human perception it can be expressed as a G-weighted level [30]. With G-weighting sound above the infrasound range is suppressed. The average infrasound perception threshold is 95 dB(G) [28]. The measured G-weighted levels are 15-20 dB below this threshold: 80.5 and 81.1 dB(G) near turbines 1 and 7 respectively, and 76.4 dB(G) at the façade.

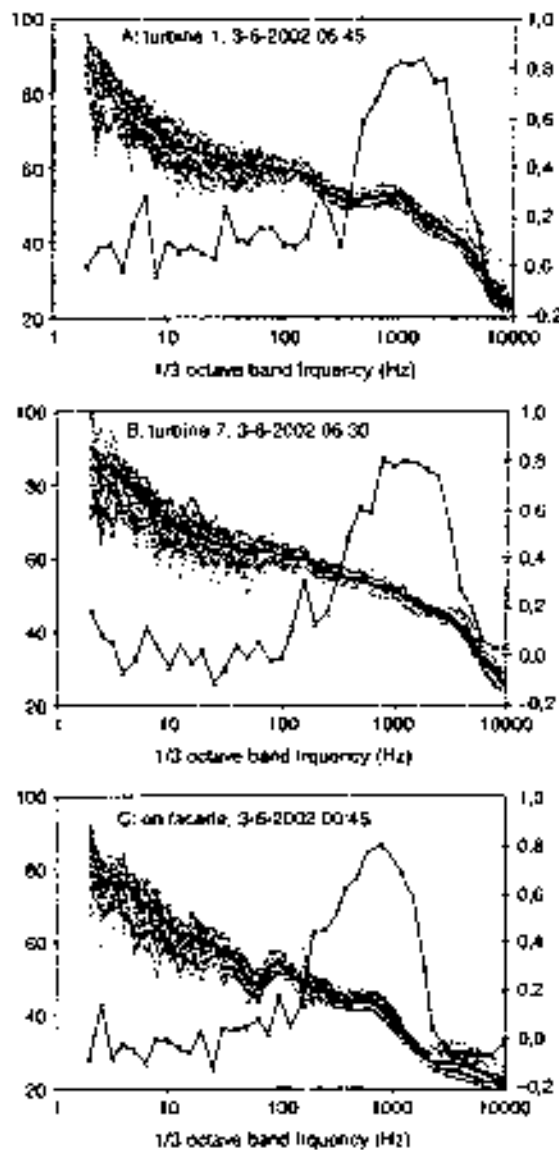

Figure 3 Left axis (in dB): 200 consecutive, unweighted and 1 second spaced 1/3 octave band levels (thin lines), and average spectral level (thick line) near turbines 1 and 7, and near dwelling B; right axis: coefficient of correlation (line with markers) at each 1/3 octave band frequency between all 200 1/3 octave band levels and overall A-weighted levels.

The correlations show that variations in total A-weighted level near the turbines are correlated with the 1/3 octave band levels with frequencies from 400 through 3150 Hz (where $\rho > 0.4$), which is trailing edge sound. This is one octave lower (200 - 1600 Hz) for the sound at the façade: the higher frequencies were better absorbed during propagation through the atmosphere.

The façade spectra in figure 3C show a local minimum at 50-63 Hz, followed by a local maximum at 80-100 Hz. In a FFT spectrum minima are at 57 and 170 Hz, maxima at 110 and 220 Hz. This is caused by interference between the direct sound wave and the wave reflected by the façade at 1.5 m from the microphone: for wave lengths of approx. 6 m (55 Hz) this leads to destructive interference, for wave lengths at 3 m (110 Hz) to constructive interference.

In figure 4A the three average spectra at the same locations as in figure 3A-C have been plotted, but now for a total measurement time of approx. 9.5 s (façade).

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

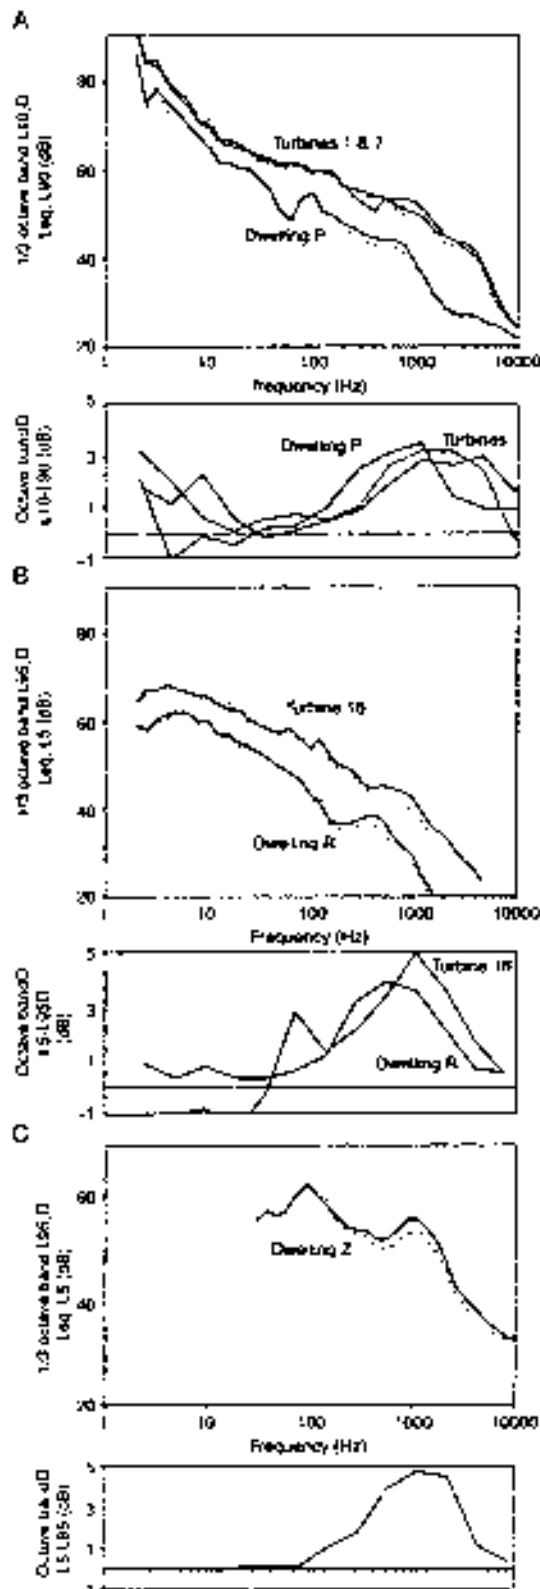

Figure 4 Upper panels A,B,C: 1/3 octave band Leq near windturbines and dwellings (thick lines) and Leq of all samples with resp. 5% highest (thin dotted lines) and 5% lowest values of broad band L₅ (dashed dotted lines). Lower panels: difference between Leq of 5- and 95-percentile octave band levels.

5 (T7) and 6 (T1) minutes. For each of these measurement periods the average of the 5% of samples with the highest broad band A-weighted sound level (i.e. the equivalent spectral level of the $L_{A,5}$ percentile) has also been plotted, as well as the 5% of samples with the lowest broad band level ($L_{A,95}$). The range in A-weighted broad band level can be defined as the difference between the highest and lowest value: $R_{bb} = L_{A,max} - L_{A,min}$. Similarly the range per 1/3 octave or octave band R_f can be defined by the difference in spectral levels corresponding to $L_{A,max}$ and $L_{A,min}$. The difference between $L_{A,5}$ and $L_{A,95}$ is a more stable value, avoiding possibly incidental extreme values, especially when spectral data are used. $R_{bb,90}$ is defined as the difference in level between the 5% highest and the 5% lowest broad band sound levels: $R_{bb,90} = L_{A,5} - L_{A,95}$. For spectral data, $R_{f,90}$ is the difference between spectral levels associated with $L_{A,5}$ and $L_{A,95}$. Values of $R_{f,90}$ are plotted in the lower part of figure 4A (three octave bandlevels have been used to avoid the somewhat 'jumpy' behaviour of the 1/3 octave band levels). Close to turbines 1 and 7 R_{bb} is 4.8 and 4.1 dB, respectively. $R_{bb,90}$ is 3.2 and 2.6 dB, which is almost the same as $R_{f,90}$ (3.2 and 3.0 dB) at 1000-4000 Hz. Further away, at the façade, R_{bb} is comparable to the near turbine values: 4.9 dB. $R_{bb,90}$ at the façade is 3.3 dB and again almost the same as maximum $R_{f,90}$ (3.5 dB) at 1000 Hz.

Also, close to the turbine there is a low frequency maximum in $R_{f,90}$ at 2 (or 8) Hz that is also present at the façade, indicating that the modulation of trailing edge sound is correlated in time with the infrasound caused by the blade movement.

Figure 4B presents similar plots for the average spectra and the $L_{A,5}$ and $L_{A,95}$ spectra at dwelling R and near turbine T16 over a period of 16 minutes. Close to the turbine the broadband $R_{bb,90}$ is 3.7 dB; octave band $R_{f,90}$ is highest (5.1 dB) at 1000 Hz. Near R broadband $R_{bb,90}$ is also 3.7 dB, and octave band $R_{f,90}$ is highest (4.0 dB) at 500 Hz. The R_{bb} ranges are 2.3-2.5 dB higher than the 90% ranges $R_{bb,90}$. A 25 second part of this 16 min period is shown in figure 5. The broadband level L_A changes with time at T16 and R, showing a more or less regular variation with a period of approximately 1 s ($\approx 1/f_b$). In these measurements the infrasound level was lower than in the previous measurements at dwelling P where beaming was more pronounced. G-weighted sound level during the 16 minutes at R was 70.4 dB(G), and at T16 77.1 dB(G).

Finally figure 3C gives average spectra over a period of 16 minutes at dwelling Z. $R_{f,90}$ is now highest (4.8 dB) at 1 kHz, and broadband $R_{bb,90}$ is 4.3 dB ($R_{bb} = 5.9$ dB). The turbine near Z is smaller and lower, but rotates faster than the Rhode turbines; for a hub height wind speed of 6 m/s the expected calculated increase in trailing edge sound for the lower up relative to the day time situation is 2.0 ± 0.8 dB for

Figure 5 Broad band A-weighted emission sound level near turbine 17 (upper plot) and close to dwelling 3 (lower plot)

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

a stable, and 2.9 ± 0.8 dB for a very stable atmosphere. For this turbine a peak trailing edge sound level is expected (according to equation A2 in appendix) at a frequency of 1550ω , $11z = 400 - 800$ Hz.

In all cases above the measured sound includes ambient background sound. Ambient background sound level could not be determined separately at the same locations because the wind turbine(s) could not be stopped (it has been shown elsewhere that it is a flaw in noise regulation to make independent noise assessment procedurally impossible because of its dependency on wind turbine owner's consent [34]). However, at audible frequencies it could be ascertained by ear that wind turbine sound was dominant. At infrasound frequencies this could not be ascertained. But if significant ambient sound were present, subtracting it from the measured levels would lead to lower (infrasound) sound levels, which would not change the conclusion, based on the G-weighted level, that measured infrasound must be considered inaudible.

4.4. Beats Caused by Interaction of Several Wind Turbines

In the previous section we saw that measured variations in broad band sound level (R_{bb}) were 4 to 6 dB. Figure 6 presents the time variation of the broad band A-weighted level from the sound level at the façade of dwelling P over a one minute period [2]. In this night stable conditions prevailed ($w = 0.45$ from the wind speeds in table 1). Turbines 12 and 11 are closest at 710 and 750 m, followed by turbines 9 and 14 at 880 and 910 m. Other turbines are more than 1 km distant and have an at least 4 dB lower emission level than the closest turbine has. The sequence in figure 6 begins when the turbine sound is noisy and constant within 2 dB. After some time (at $t = 155$ s) regular pulses appear with a maximum height of 3 dB, followed by a short period with louder (5 dB) and steeper (rise time up to 23 dB/s) pulses. The pulse frequency is equal to the blade passing frequency. Then ($t > 180$ s) the pulses become weaker and there is a slight increase in wind speed.

This was one of the nights where a distinct beat was audible: a period with a distinct beat alternating with a period with a weaker or no beat, repeated more or less during the entire night. The pattern is consistent with three pulse trains of slightly different frequencies [2].

In figure 7 the equivalent 1/3 octave band spectrum at the façade of P has been plotted for the period of the beat ($165 < t < 175$ s in figure 6, spectra sampled at a rate of 20 s^{-1}), as well as the equivalent spectrum associated with the 5% highest ($L_{A5} = 52.3 \text{ dB(A)}$) and the 5% lowest ($L_{A5} = 47.7 \text{ dB(A)}$) broad band levels and the difference between both. As in the similar spectra in figure 4 we see that the beat corresponds to an increase at frequencies where trailing edge sound dominates. The sound pulses correspond to 1/3 octave band levels between 200 and 1250 Hz and are highest at 800 Hz. In figure 7 also the equivalent 1/3 octave band levels are plotted for the period after beating where the wind was picking up slightly ($t > 175$ s in figure 6). Here spectral levels above 400 Hz are the same or slightly lower as on average at the time of beating, but at lower frequencies down to 80 Hz (related to in-flow turbulence) levels now are 1 to 2 dB higher. The increase in the 'more wind' spectrum at high frequencies (> 2000 Hz) is probably from rustling tree leaves.

Figure 8 shows sound spectra for a period with a distinct beat ($150 < t < 175$ s in figure 6), and a period with a weak or no beat ($130 < t < 150$ s). Each spectrum is

Figure 6 Broad band A-weighted continuous sound level at façade of dwelling P

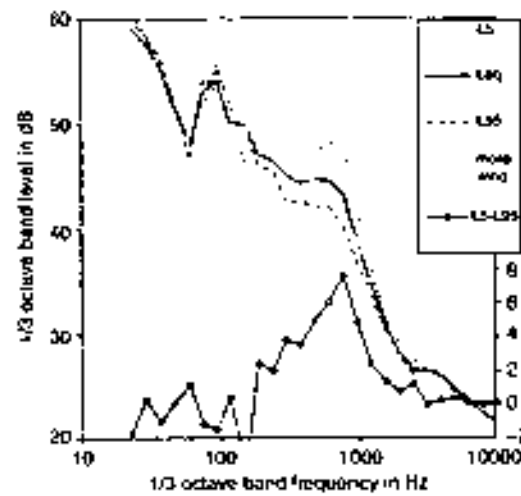

Figure 7 1/3 octave band levels at facade of dwelling P during beating (L_{50} , L_{15} and L_{95}) and when wind speed is peaking (L_{50}).

Figure 8 Sound power spectrum of A-weighted 0.2 Hz band immersion sound level at facade of dwelling P when beating is distinctly or not audible and with slightly increased wind speed.

an FFT of 0.2 Hz line width from broad band A-weighted immersion sound pressure level values. The frequencies are therefore *modulation*, not sound frequencies. The abscissa spans 20 dB. The spectra show that distinct beating is associated with higher total A-weighted levels at the blade passing frequency and its harmonics. As has been shown above, the higher level is related to the frequency range of trailing edge sound, not to infrasound frequencies linked to thickness sound. When beating is weaker but there is more wind ($t > 175$ s), the level of the odd harmonics (base frequency $k = 1$, and $k = 3$) is lower than during 'beat', whereas the first two even harmonics ($k = 2, 4$) are equally loud, indicating more distorted (less sinusoidal) and lower level pulses. It is important to realize that the periodic variation as represented in figure 8 is the result from a wind farm, not from a single turbine.

In long term measurements near the Biele wind farm, where average and percentile sound levels were determined over 5 minute periods, periods where wind turbine sound was dominant could be selected with a criterion ($R_{90,95} = L_{15} - L_{95} \leq 4$ dB) implying a fairly constant source with less than 4 dB variation for 90% of the time [2]. The statistical distribution of the criterion values has been plotted in 1 dB intervals in figure 9 for the two long term measurement locations A and B (see figure 2). Total measurement times - with levels in compliance with the criterion- were 110 and 175 hours, respectively. Relative to dwellings P and R, one location (A, 400 m from nearest turbine) is closer to the turbines, the other (B, 1500 m) is further. The figure

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

Figure 9 Statistical distribution of level differences (in 1 dB classes) between high and low sound levels within 5 minute periods at 400 m (left) and 1500 m (right) from the nearest wind turbine.

shows that the criterion value (cut off at 4 dB) at both locations peaks at 2.5 dB. Also plotted in figure 9 is the value of $L_{A,max} - L_{A,min}$ (while $R_{sb,50} \leq 4$ dB), peaking at 3.5 dB at both locations. Finally, the difference between maximum and minimum level within 5 minute periods, $L_{A,max} - L_{A,min} = R_{sb}$, peaks at 4.5 dB (location A) and 5.5 dB (B). Where $R_{sb} > 7$ dB, the distributions are influenced by louder (non-turbine) sounds, such as from birds. Extrapolation of the distribution from lower values suggests that the maximum range R_{sb} due to the wind farm is 8.5 dB (location A) to 9.5 dB (B). This is 4 dB more than the most frequently occurring ranges at both locations.

4.5. Summary of Results

In table 11 the level variations due to blade swish as determined in the previous sections have been summarised. Some values not presented in the text have been added. The ranges are presented as R_{sb} and $R_{sb,90}$. The latter is of course a lower value as it leaves out high and low excursions occurring less than 10% of the time. The time interval over which these level differences occur differ; from several up to 16 minutes for the short term measurements, where wind conditions can be presumed constant, up to over 100 hours at locations A and B.

5. PERCEPTION OF WIND TURBINE SOUND

In a review of literature on wind turbine sound Pedersen concluded that wind turbine noise was not studied in sufficient detail to be able to draw general conclusions, but that the available studies indicated that at relatively low levels wind turbine sound was more annoying than other sources of community noise such as traffic [21]. In a field study by Pedersen and Persson-Waye [22] 8 of 40 respondents living in dwellings with (calculated) maximum outdoor intrusion levels of 37.5 - 40.0 dB(A) were very annoyed by the sound, and at levels above 40 dB(A) 9 of 25 respondents were very annoyed. The correlation between sound level (in 2.5 dB classes) and annoyance was significant ($p < 0.001$). In this field study annoyance was correlated to descriptions of the sound characteristics, most strongly to swishing with a correlation coefficient of 0.72 [22]. A high degree of annoyance is not expected at levels below 40 dB(A), unless the sound has special features such as a low-frequency component or an intermittent character [23]. Psychoacoustic characteristics of wind turbine sound have been investigated by Persson-Waye *et al.* in a laboratory setting with naive listeners (students not used to wind turbine sound): the most annoying sound recorded from five different turbines were described as 'swishing', 'tapping' and 'whistling', the least annoying as 'grinding' and 'low frequency' [24]. People living close to wind turbines, interviewed by Pedersen *et al.*, felt irritated

Notes:

¹ hub height 100 m, rotor diameter 70 m, 23 rpm

² for this turbine (hub height 45 m, diameter 45 m, 24 rpm) $R_{sw} < 3.7$ dB was calculated

because of the intrusion of the wind turbines in their homes and gardens, especially the swishing sound, the blinking shadows and constant rotation [25].

Our experience at distances of approx. 700 to 1500 m from the Rhode wind farm, with the turbines rotating at high speed on a clear night and pronounced beating audible, is that the sound resembles distant pile driving. When asked to describe the sound of the turbines in this wind farm, a resident compares it to the surf on a rocky coast. Another resident near a set of smaller wind turbines, likens the sound to that of a racing rowing boat (where rowers simultaneously draw, also creating a periodic swish). Several residents near single wind turbines remark that the sound often changing to clapping, drumming or beating when night falls: 'like a washing machine'. It is common in all descriptions that there is noise ('like a nearby motorway', 'a B747 constantly taking off') with a periodic increase superimposed. In all cases the sound acquires this more striking character late in the afternoon or at night, especially in clear nights and downwind from a turbine.

Part of the relatively high annoyance level and the characterisation of wind turbine sound as lapping, swishing, clapping or beating may be explained by the increased fluctuation of the sound [2, 21]. Our results in table 2 show that in a stable atmosphere measured fluctuation levels are 4 to 6 dB for single turbines, and in long term measurements (over many 5 minute periods) near the Rhode wind farm fluctuation levels of approx. 5 dB are common but may reach values up to 9 dB.

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

The level difference associated with an amplitude modulation (AM) factor mf is $\Delta L = 20 \log((1+mf)/(1-mf))$. The modulation factor mf is the change in sound pressure amplitude due to modulation, relative to the average amplitude. For $\Delta L < 9$ dB a good approximation ($\pm 5\%$) is $mf = 0.055 \Delta L$. Now when ΔL rises from 3 dB, presumably a maximum value for a daytime (unstable or neutral) atmosphere, to 6 dB, mf rises from 17% to 33%. For a maximum value of $\Delta L = 9$ dB, mf is 50%.

Fluctuations are perceived as such when the modulation frequencies are less than 20 Hz. Human sensitivity for fluctuations is highest at $f_{mod} = 4$ Hz, which is the frequency typical for rhythm in music and speech [26], and for frequencies of the modulated sound close to 1 kHz. For wind turbines we found that a typical modulation frequency is 1 Hz, modulating the trailing edge sound that itself is at frequencies of 500 – 1000 Hz. So human sensitivity for wind turbine sound fluctuations is relatively high.

Fluctuation strength can be expressed in a percentage relative to the highest perceptible fluctuation strength (100%) or in the unit vacil [26]. The reference value for the absolute fluctuation strength is 1 vacil, equalling a 60 dB, 1 kHz tone, 100% amplitude-modulated at 4 Hz [26].

For an AM pure tone as well as AM broad band noise, absolute fluctuation strength is zero until $\Delta L = 3$ dB, then increases approximately linearly with modulation depth for values up to 1 vacil. For a broad band noise level L_A the fluctuation strength F_{fb} can be written as [26].

$$F_{fb} = \frac{5.8(1.25mf - 0.25)(0.05 L_A - 1)}{(f_{mod}/5\text{Hz})^4 + (4\text{Hz}/f_{mod}) + 1.5} \quad \text{vacil} \quad (2)$$

With typical values of $f_{mod} = 1$ Hz and $L_A = 40$ dB(A), this can be written as $F_{fb} = 1.3(mf-0.2)$ vacil or, when $\Delta L < 9$ dB:

$$F_{fb} = 0.072(\Delta L - 3.6) \quad \text{vacil} \quad (3)$$

When ΔL increases from 3 to 6 dB, F_{fb} increases from negligible to 0.18 vacil. For the high fluctuation levels found at locations A and B ($\Delta L = 8 - 9$ dB), F_{fb} is 0.32 to 0.39 vacil.

It can be concluded that, in a stable atmosphere, the fluctuations in modern wind turbine sound can be readily perceived. However, as yet it is not clear how this relates to possible annoyance. It can however be likened to the rhythmic beat of music: pleasant when the music is appreciated, but distinctly intrusive when the music is unwanted.

The hypothesis that these fluctuations are important, is supported by descriptions of the character of wind turbine sound as ‘lapping’, ‘swishing’, ‘clapping’, ‘beating’ or ‘like the surf’. Those who visit a wind turbine in daytime will usually not hear this and probably not realise that the sound can be rather different in conditions that do not occur in daytime. This may add to the frustration of residents: “Being highly affected by the wind turbines was hard to explain to people who have not had the experiences themselves and the informants felt that they were *not being believed*” [25]. Persson-Waye *et al.* observed that, from five recorded different turbine sounds “the most annoying noises were also paid attention to for a longer time”. This supported the hypothesis that awareness of the noise and possibly the degree of annoyance depended on the content (of intrusive character) of the sound [24].

Fluctuations with peak levels of 3 – 9 dB above a constant level may have effects on sleep quality. The Dutch Health Council [33] states that “at a given L_{night} value, the most unfavourable situation in terms of a particular sleep biological effect of night-time noise is not, as might be supposed, one characterised by a few loud noise events per night. Rather, the worst scenario involves a number of noise events all of which are roughly 5 dB(A) above the threshold for the effect in question.” For transportation noise (road, rail, air traffic) the threshold for mobility impairment, a direct biological effect having a negative impact on sleep quality, is a sound exposure level per sound event of SEL₁ = 40 dB(A) in the bedroom [33]. The pulses in figure 6

have SEL-values up to 50 dB(A), but were measured on the façade. With an open window facing the wind turbines indoor SEL-values may exceed the threshold level. In other situations this of course depends on distance to and sound power of the turbines and on the attenuation between façade and bedroom. It is not clear whether the constant and relatively rapid repetition of wind turbine sound beats will have more or less effect on sleep quality, compared to vehicle or airplane passages. Pedersen and Persson Waye found that at dwellings where the (outdoor) sound level due to wind turbines exceeded 35 dB(A), 16% of 128 respondents reported sleep disturbance by this sound, of whom all but two slept with a window open in summer [22].

6. DISCUSSION AND CONCLUSION

Atmospheric stability has a significant effect on wind turbine sound, especially for modern, tall turbines.

First, it is related to a change in wind profile causing strong, higher altitude, winds while at the same time wind close to the ground may become relatively weak. High sound emission levels may thus occur at low ambient sound levels, a fact that has not been recognised in noise assessments where a neutral or unstable atmosphere is usually implied. As a result, wind turbine sound that is masked by ambient wind-related sound in daytime, may not be masked at night time. This has been dealt with elsewhere [2].

Secondly, the change in wind profile causes a change in angle of attack on the turbine blades. This increases the thickness (intra) sound level as well as the level of trailing edge (TE) sound, especially when a blade passes the tower. TE sound is modulated at the blade passing frequency, but it is a high frequency sound, well audible and indeed the most dominant component of wind turbine noise. The periodic increase in sound level when the blade passes the turbine tower, blade swish, is a well known phenomenon. Less well known is the fact that increasing atmospheric stability creates greater changes in the angle of attack over the rotor plane that add up with the change near the tower. This results in a thicker turbulent TE boundary layer, in turn causing a higher swish level and a shift to somewhat lower frequencies. It can be shown theoretically that for a modern, tall wind turbine in flat, open land the angle of attack at the blade tip passing the tower changes by approx. 2° in daytime, but this value increases by 2° when the atmosphere becomes very stable. The calculated rise in sound level during swish then increases from 1-2 dB to 4-6 dB. This value is confirmed by measurements at single turbines on the Rhode wind farm where maximum sound levels rise 4 to 6 dB above minimum sound levels within short periods of time.

Thirdly, atmospheric stability involves a decrease in large scale turbulence. Large fluctuations in wind speed (at the scale of a turbine) vanish, and the coherence in wind speed over distances as great as or larger than the size of an entire wind farm increases. As a result turbines in the farm are exposed to a more constant wind and rotate at a more similar speed with less fluctuations. Because of the near-synchronicity, blade swishes may arrive simultaneously for a period of time and increase swish level. The phase difference between turbines determines where this amplification occurs: whether the swish pulses will coincide at a location depends on this phase difference and the propagation time of the sound. In an area where two or more turbines are comparably loud the place where this amplification occurs will sweep over the area with a velocity determined by the difference in rotational frequency. The magnitude of this effect thus depends on stability, but also on the number of wind turbines and the distances to the observer. This effect is in contrast to what was expected, as it seemed reasonable to suppose that turbines would behave independently and thus the blade swish pulses from several turbines would arrive at random, resulting in an even more constant level than from one turbine. Also, within a wind farm the effect may not be noticed, since comparable positions in relation to two or more turbines are less easily realised at close distances.

Sound level differences $L_{\text{swish}} - L_{\text{min}}$ (corresponding to swish pulse heights) within 5 minute periods over long measurement periods near the Rhode wind farm show that level changes of approximately 5 dB occur for an appreciable amount of time and may

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

less often be as high as 8 or 9 dB. This level difference did not decrease with distance, but even increased 1 dB when distance to the wind farm rose from 400 m to 1500 m. The added 3-5 dB, relative to a single turbine, is in agreement with simultaneously arriving pulses from two or three approximately equally loud turbines.

The increase in blade swish level creates a new percept, fluctuating sound, that is absent or weak in neutral or unstable atmospheric conditions. Blade passing frequency is now an important parameter as a modulation frequency (not as an infra-sound frequency). Human perception is most sensitive to modulation frequencies close to 4 Hz of sound with a frequency of approx. 1 kHz. The hypothesis that fluctuations are important is supported by descriptions given by naive listeners as well as residents: turbines sound like 'lapping', 'swishing', 'clapping', 'beating' or 'like the surf'. It is not clear to what degree this fluctuating character determines the relatively high annoyance caused by wind turbine sound and to a deterioration of sleep quality. Further research is necessary into the perception and annoyance of wind turbine sound, with correct assumptions on the level and character of the sound. Also the sound exposure level of fluctuations in the sound in the bedroom must be investigated to be able to assess the effects on sleep quality.

It is obvious that in wind turbine sound measurements atmospheric stability must be taken into account. When the impulsive character of the sound is assessed, this should be carried out in relation to a stable atmosphere, as that is the relevant condition for impulsiveness. Also sound immission should be assessed for stable conditions in all cases where night time is the critical noise period. Wind speed at low heights is not a sufficient indicator for wind turbine performance. Specifically, when ambient sound level is considered as a masker for wind turbine sound, neither sounds should be related to wind speed at reference height via a (possibly implicit) neutral wind profile. In stable conditions wind induced sound on a microphone is not as loud as is usually thought (creating a high background level lowering the 'signal to noise ratio'), as in these conditions hub height wind speeds are accompanied by relatively low microphone height wind speeds. So, wind turbine sound measurements are easier when performed in a stable atmosphere, which agrees well with the night being the sensitive period for noise immission.

LIST OF SYMBOLS

Symbol: definition [unit]

α :	angle of attack [radian or degree]
δ_i^* :	displacement thickness of turbulent boundary layer [m]
ν :	kinematic viscosity of air [$\text{m}^2 \text{s}^{-1}$]
ρ :	correlation coefficient (here: between $(1/3)$ octave band level and L_{α})
Ω :	turbine rotor angular velocity [rad s^{-1}]
a :	correction factor for boundary layer thickness (value: 2 - 4)
c :	velocity of sound in air [m s^{-1}]
C :	blade chord length [m]
D_{θ} :	directivity function [-]
f :	frequency [Hz]
f_{mod} :	modulation frequency [Hz]
$f_{peak,TE}$:	peak frequency of trailing edge sound [Hz]
$f_{peak,t}$:	peak frequency of in-flow turbulence sound [Hz]
f_B :	blade passing frequency [Hz]
f_c :	α -dependent factor for boundary layer thickness [-]
F_{θ} :	fluctuation strength [voel]
h :	height [m]
H :	turbine height [m]
h_{ref} :	reference height for wind speed (and direction) [m]
k :	integer number (of harmonic frequency)
K_{α} :	constant (128.5 dB)
K_{α} :	α dependent increase in trailing edge sound level [dB]
M :	Mach number (at radius R; $M = \Omega R/c$) [-]
ΔL :	increase in sound level [dB]
L_{α} :	broad band sound level [dB(A)]
$L_{5\%}$:	5-percentile of broad band sound levels over a time period [dB(A)]
$L_{95\%}$:	95-percentile of broad band sound levels over a time period [dB(A)]
m :	stability exponent [-]
μF :	modulation factor [-]
N :	number of blades [-]

r :	distance [m]
R :	rotor radius = blade length [m]
ΔR :	increment in R [m]
R_X :	range between maximum and minimum sound levels ($X = \text{bb or } \text{f}$) [dB]
$R_{X,95}$:	range between 5- and 95-percentile of sound levels ($X = \text{bb or } \text{f}$) [dB]
Re :	chord based Reynolds number ($Re = \Omega RC/v$) [-]
v_x :	wind speed at height h [m s^{-1}]
v_{ref} :	wind speed at reference height [m s^{-1}]
v_{xx} :	wind speed at height xx m [m s^{-1}]
Sp_i :	1/3 octave band weighting function for TE sound [dB]
SPL_i :	sound pressure level [dB]
St :	Strouhal number [-]

Subscripts:

A:	A-weighted
hh:	broad band
i:	at frequency of 1/3 octave band
i:	component of TE sound ($i = p, s, \alpha$)
if:	in-flow
p:	pressure side
s:	suction side
TE:	trailing edge

APPENDIX I**Dominant Sources of Wind Turbine Sound**

With modern wind turbines there are three important mechanisms that produce sound. These will be reviewed here up to a detail that is relevant to this paper.

A. Infrasound: thickness sound

When a blade moves through the air, the air on the forward edge is pushed sideways, moving back again at the rear edge. For a periodically moving blade the air is periodically forced, leading to 'thickness sound'. Usually this will not lead to a significant sound production as the movement is smooth and thus accelerations are relatively small.

When a blade passes the turbine tower, it encounters wind influenced by the tower: the wind is slowed down, forced to move sideways around the tower, and causes a wake behind the tower. For a downwind rotor (i.e. the wind passes the tower first then the rotor) this wake causes a significant change in blade loading.

The change in wind velocity near the tower means that the angle of attack of the air on a blade changes and lift and drag on the blade change more or less abruptly. This change in mechanical load increases the sound power level at the rate of the blade passing frequency, f_B . For modern turbines $f_B = N\Omega/2\pi$ typically has a value of approximately 1 Hz. As the movement is not purely sinusoidal, there are harmonics with frequencies kf_B , where k is an integer. Harmonics may occur up to 30 Hz, so thickness sound coincides with the infrasound region (0–30 Hz). Measured levels at 92 m from the two-bladed 2 MW WTS-4 turbine showed that measured sound pressure levels of the individual blade harmonics were less than 75 dB, and well predicted by calculations of wind-blade interaction near the turbine tower [5, 6]. The envelope of the harmonics peaks at the fifth harmonic ($k = 5$ with $f_B = 1$ Hz), indicating a typical pulse time of $(5 \text{ Hz})^{-1} = 0.2 \text{ s}$ which is 20% of the time between consecutive blade passages. The WTS-4 is a downwind turbine with an 80 m tubular tower, where the wind velocity deficit was estimated to be 40% of the free wind velocity [5]. For modern, upwind rotors the velocity deficit in front of the tower is smaller. As a consequence blade-tower wake interaction is weaker than for downwind turbines. From data collected by Jakobsen it appears that the infrasound level at 100 m from an upwind turbine is typically 70 dB(C) or lower, near downwind turbines 10 to 30 dB higher, where 95 dB(C) corresponds to the average infrasound hearing threshold [28]. Infrasound from upwind wind turbines thus does not appear to be so loud that it is directly perceptible.

The Effect of Atmospheric Stability on Low Frequency Modulated Sound

B. Low frequencies: in-flow turbulent sound.

Because of atmospheric turbulence there is a random movement of air superimposed on the average wind speed. The contribution of atmospheric turbulence to wind turbine sound is named 'in-flow turbulence sound' and is broad band sound stretching over a wide frequency range. For turbulent eddies larger in size than the blade this may be interpreted as a change in the direction and/or velocity of the incoming flow, equivalent to a deviation of the optimal angle of attack. This leads to the same phenomena as in A, but changes will be random (not periodic) and less abrupt. For turbulent eddies the size of the chord length and less, effects are local and do not occur coherently over the blade. When the blade cuts through the eddies, the movement normal to the wind surface is reduced or stopped, given rise to high accelerations and thus sound.

In-flow turbulence sound has a maximum level in the $1/3$ octave band with frequency:

$$f_{\text{peak},if} = (540.7R\Omega)/(H-0.7R) \quad (A1)$$

where Strouhal number St is 16.6 [4, 6]. Most sound is produced at the high velocity, outer parts of the blades. For a modern, tall, three-bladed wind turbine with hub height $H = 100$ m, blade length $R = 35$ m and angular velocity $\Omega = 2\pi f_r/3 = 2 \text{ rad s}^{-1}$ (20 rpm), $f_{\text{peak},if} = 11$ Hz which is in the infrasound region. Measured fall-off from $f_{\text{peak},if}$ is initially approx. 3 dB per octave, increasing to 12 dB per octave at frequencies in the audible region up to a few hundreds of hertz [4, 6].

C. High frequencies: trailing edge sound

Several flow phenomena at the blade itself or in the turbulent wake behind a blade cause high frequency sound ('airfoil self-noise'). Most important for modern turbines is the sound from the turbulent boundary layer at the rear of the blade surface where the boundary layer is thickest and turbulence strength highest. Trailing edge sound has a maximum level in the $1/3$ octave band with frequency

$$f_{\text{peak},TE} = 0.02 \Omega R / (\delta^* M^{0.5}) \quad (A2)$$

where Mach number M is based on airfoil velocity. The displacement thickness of the turbulent layer is:

$$\delta^* = 40.37 C Re^{-0.22} / \alpha \quad (A3)$$

for a zero angle of attack. Re is the chord based Reynolds number [29]. The experimental factor α accounts for the empirical observation that the boundary layer is a factor 2 to 4 thicker than predicted by theory [3, 6]. For air of 10°C and atmospheric pressure, a typical chord length $C = 1$ m, and other properties as given above (section B), $f_{\text{peak},TE} = 17000\alpha$ Hz. With $\alpha = 2$ to 4, $f_{\text{peak},TE}$ is 450 - 900 Hz. The spectrum (see $S_{p,TE}$ below) is symmetrical around $f_{\text{peak},TE}$ and decreases with 3 dB for the first octave, 11 dB for the next, the contribution from further octave bands is negligible [29].

According to Bronks *et al.* [29] trailing edge sound level can be decomposed in components SPL_p and SPL_s due to the pressure and suction side turbulent boundary layers with a zero angle of attack of the incoming flow, and a component SPL_α that accounts for a non-zero angle of attack α . For an edge length ΔR each of the three components of the immission sound level at distance r can be written as [29]:

$$SPL_i = 10 \log(\delta_i^* M^4 \Delta R D_i / r^2) + Sp_i + K_i - 3 + K, \quad (A4)$$

and total trailing edge immission sound level as:

$$SPL_{TE} = 10 \log(\sum_i 10^{SPL_i/10}) \quad (A5)$$

where the index i refers to the pressure side, suction side or angle of attack part ($i = p, s, \alpha$). The directivity function D_i equals unity at the rear of the blade ($\theta = 180^\circ$) and falls off with $\sin^2(\theta/2)$. Because of the strong dependence on

Table A1. Increase of trailing edge sound level with angle of attack α

α	1	2	3	4	5
$SPL_{12}(\alpha) - SPL_{12}(\alpha=0)$ (dB)	0.4	1.4	2.9	4.6	6.4

M ($\sim M^2$) trailing edge sound is dominated by sound produced at the high velocity parts: the blade tips.

Sp_1 gives the symmetrical spectral distribution of the trailing edge sound spectrum centered on $f_{peak,12}$ and is maximum (0 dB) at this centre frequency. The constant $K_1 - 3 \approx 125.5$ dB applies when the chord based Reynolds number exceeds 8×10^5 and the pressure-side turbulent boundary displacement thickness $\delta_2^* > 1$ mm, as is the case for modern tall turbines. K_1 is non-zero only if $i = a$.

For small non-zero angles of attack ($\alpha < 5^\circ$) the boundary layer thickness shrinks δ^* with a factor $f_p = 10^{-0.142\alpha}$ at the pressure-side and grows with a factor $f_s = 10^{0.043\alpha}$ at the suction-side; $\delta_2^* = \delta_1^*$, so $f_{a1} = 1$.

K_{a1} has a large negative value for $\alpha = 0$. For $1^\circ < \alpha < 5^\circ$ and $M = 0.2$ it can be approximated by $K_{a1} = 3.6\alpha - 12.1$ (429), formula 49 with $K_{a1} = K_2 - K_1 + 3$.

With equation A4, equation A5 can be rewritten as:

$$SPL_{12} = 10 \log(\delta^* M^2 \Delta R D_w / r^2) + K_1 - 3 + 10 \log\left(\sum_i 10^{(10 \log(\delta_1^* + \delta_2^* - K_1)/10)}\right) \quad (A6)$$

The last term in A6 is the α -dependent part. For the peak frequency 1/3 octave band level ($Sp_a = 0$) the last term in equation A6 is 3 dB for $\alpha = 0$, and 4.4 dB at $\alpha = 2^\circ$, then increasing with approx. 1.7 dB per degree to 9.4 dB at $\alpha = 5^\circ$. The level increase relative to the level at $\alpha = 0$ is given in table A1.

The swishing sound that one hears when a blade passes the tower is less than 3 dB (in daytime) (8). It must correspond to a change in sound level of 1 dB to be heard at all. An increase of 1 dB corresponds to an increase in α from zero to a value of 1.7° (0.03 radians), an increase of 2 dB corresponds to 2.5° (0.04 radians). So we estimate the change in α at the tower passage as $2.1 \pm 0.4^\circ$. Part of this is due to the lower wind velocity at the lower blade tip relative to the rotor average (0.8", see section 3 of main text), the rest is due to the slowing down of the wind by the tower.

For small angles the change of wind speed with angle of attack α at radius R is:

$$dV_{\infty,tip}/d\alpha = 52R \quad (A7)$$

So for a modern turbine ($52R = 70$ m/s at tip at 20 rpm) the wind speed deficit where the blade tip passes the tower and $\alpha = 2.1^\circ$ (0.037 radians) is 2.6 m/s. In a rotor averaged 14 m/s wind this is 20%. This deficit is due to the influence of the tower as well as the (daytime) wind profile.

I WIND POWER, SOCIETY, THIS BOOK: an introduction

Bobby asks: 'Do you ever hear the windmills?'

'What sound do they make?'

'It's a clanking metal noise, but when the wind is really strong the blades blur and the air starts screaming in pain.' He shudders.

'What are the windmills for?'

'They keep everything running'

'If you put your ear to the ground you can hear them.'

'What do you mean by everything?'

*'The lights, the factories, the railways. Without the windmills it all stops.'*¹

This is the story of the discovery of a new phenomenon: why wind turbines sound different at night time. This discovery was related to a problem in society, namely that of perceived noise by residents living close to such turbines..

This introduction sketches the context in which my work proceeded: how the questions came up, why noise is an inseparable part of wind power development, and that being critical does not need to imply a negative attitude towards wind power. Let's start at the beginning.

1.1 A 'new' phenomenon

The discovery was modest: I have not found a new law of nature or a new way to make money. It was rather the idea to apply existing knowledge in a new context: the application of atmospheric physics to solve the mystery why people complained about noise from wind turbines that according to wind developers and acoustic consultants they should not even be able to hear. In principle it was not very difficult to find out why. When Walter Flight (a very Dutch citizen despite his name) told me he could see the wind turbines near his house rotating at high speed while at the same time his garden was completely calm, I thought: oh yes, I know that, that's

¹ 'The suspect', by Michael Robotham, Time Warner Paperbacks, 2003 (p. 151)

because at night, especially on nice summer evenings, the atmosphere becomes stable. I teach this in a course, Environmental Techniques. The phenomenon is treated extensively in this book, but for now it is sufficient to know that, due to strong winds at greater heights coupled with very light winds at ground level, wind turbines can be a lot noisier in a night time atmosphere than they are in daytime. This was why Walter and his neighbours complained. Also the nature of the sound changes: a thumping character can become very pronounced at night.

In this book I will often use the terms 'day' and 'night', though the distinction is more accurately stated as the atmosphere being unstable (which is usually in daytime, that is: sun up) or stable (night time, sun down). The heat coming in from the sun or radiated out at night is the real cause of the difference in stability. In between is another state, namely neutral, where heating or cooling are unimportant because of heavy clouding and/or strong wind and which can occur in day as well as night time, though not very often in a temperate climate and over land. Atmospheric stability means that vertical movements in the air are damped and as a consequence horizontal layers of air can have a greater difference in velocity: close to the ground the wind can be weak while higher up there is a strong wind.

Though in principle the explanation is simple and easily understood, it of course had to be shown from solid theory and with sufficient data that the explanation was correct. The first steps were extensive measurements in Bellingwolde, where severe complaints had arisen about noise from the nearby Rhode wind farm. This I did together with Richard de Graaf, then a physics student.

After this simple discovery, a new mystery (to me) was why this did not play a role in the assessment of wind turbine noise? Every meteorologist knows about atmospheric stability, so why had none of the experts dealing with wind turbine sound ever come across it? Wind turbines have been built for several decades and since the 1980's in ever larger numbers, so there should be a lot of accumulated experience. Had no one (except some

residents) noticed the discrepancy between predicted and real noise exposure?

There are probably several reasons. One of them is that for a long time wind turbines were not big enough for the effects of atmospheric stability to be clearly noticeable. Since wind turbines have grown taller the effect manifests itself more clearly. Secondly, as the more distant locations have become scarce, more and more turbines are being built closer to where people live, so more people now experience the sound of wind turbines. Thirdly, atmospheric stability over flat land is easier to understand and quantify than in a mountainous or coastal area where the atmosphere is more complex so the effect on wind turbines may be less easily recognizable.

Wind turbines as such have not become that much noisier, despite their increase in height and blade span (the sound power depends more on speed than on physical dimensions of the towers). Earlier machines could be quite noisy due to whining or severe thumping, and modern designs are certainly better. The point is they now reach into less familiar parts of the atmosphere.

Finally, an important reason to not recognize the unexpected high sound levels certainly is the fact that it impedes commercial interests and national policy. The positive ring of the term 'sustainability' helps investors in wind energy and local authorities (applying national policy) to counterbalance objections concerning possible disadvantages of new projects. As these objections are sometimes strong enough to torpedo projects, investors and authorities don't welcome more negative news. Though the population widely supports sustainable energy, reactions are less positive when a new project adversely affects their lives. This 'contradictory behaviour' is in fact quite understandable: when a new project is planned in an area, residents for the first time have to balance the positive social consequences to the negative local impact: visual impact, flickering shadows, noise and possibly ice throw from turbine blades.

The first reaction of wind energy proponents, represented by the Windkoepel ('Wind dome'), to our research results was to pay a consultant

to comment on our report [Van den Berg *et al* 2002]. This consultant boasted of having advised a large number of wind farm projects, so he clearly understood the position of the wind power industry. In the resulting 'second opinion' [Kerkers 2003] no material critique was presented, only procedural arguments were used to declare our results inaccurate and thus irrelevant. The Windkoepel issued a press statement concluding that we had made a lot of fuss, but had not contributed any new insights.¹ They could get back to business.

1.2 Digging deeper

I too went back to my business, which can be summarized as helping citizen groups to defend their position by objective arguments using known principles of physics. In 2004 an article about my research was published in a scientific journal [Van den Berg 2004a] lending my results the respectability of peer review and triggering an international e-mail influx from interested consultants as well as worried residents, as our first report had done earlier on a national scale.

What still puzzled me at that time was how a single turbine could start thumping at night. I thought I understood how the modest blade swish of a single turbine could evolve into louder thumping: the small sound variations due to blade swish from several turbines could add up to louder pulses. But with a single turbine there is nothing to add! Apart from this, in news media in the UK there were complaints that low frequency wind turbine noise had been underestimated and had been making people sick.²

Some thoughts about this were presented at a conference in Maastricht [Van den Berg 2004b]. I agreed with delegate Jørgen Jakobsen, who presented a paper on low frequency wind turbine noise [Jakobsen 2004],

¹ Press statement February 2, 2003 "Orlangs is opschudding ontstaan", ("Recently an upheaval was caused..."), De Windkoepel, Arnhem

² Catherine Milner: "Wind farms make people sick who live up to a mile away", online Telegraph, filed January 25, 2004 (<http://news.telegraph.co.uk/news/main.jhtml?xml=/news/2004/01/25/nwind25.xml>, consulted December 10, 2005)

that even though wind turbines did produce an appreciable amount of infrasound, the level was so far below the average human hearing threshold that it could not be a large scale problem. But it was possible that complaints had been expressed in a way not understood by experts. Perhaps people bothered by the endless thumping of a relatively low pitched sound (such as I had heard myself on several occasions), thought that 'low frequency sound' was a term to use, as official sounding jargon. They might not be aware that the term 'low frequency sound' makes acousticians think of frequencies below 100 to 200 hertz, and in that range the sound level was not considered to be problematic. A classical misunderstanding perhaps, that could be clarified. After the Maastricht conference I wanted to quantify my ideas on the origin of the night time thumping of wind turbines and the relevance of low frequencies. This resulted in a second scientific article [Van den Berg 2005a] in which I tried to put these ideas together.

What had surprised me from early on was that people in the wind power business seemed to know so little about their raw material, the wind. In the Windkoepel press statement (see footnote previous page) a wind turbine manufacturer's spokesman argued that if the hub height wind velocity indeed was structurally higher at night, this must be visible in production statistics. This indeed seems plausible, so why not investigate that? If the wind industry had done so, they might have come up with results I found from measured wind profiles at Cabauw over an entire year [Van den Berg 2005b]. Indeed for an 80 m high turbine the night time yield is significantly higher than expected, whereas the daytime yield is lower. The net result was that in the real atmosphere at Cabauw annual production was 14% to 20% (depending on wind turbine power settings) higher than in an atmosphere extrapolated from 10-m wind velocities with a perpetual neutral wind profile. For wind power production forecasting there is a method that incorporates a correction for atmospheric stability [Troen *et al* 1989], but such knowledge has never been used for sound exposure forecasting.

1.3 Commercial and policy implications

So from an energy point of view a stable atmosphere is very attractive. The challenge is to use that potential, but not put the burden on those living nearby. One solution is to build wind farms offshore where no people are affected if enough distance is kept (and calculation models are used that accurately model long range sound propagation over water). Over large bodies of water seasonal, not diurnal atmospheric stability will boost production in part of the year but lower it when the water has warmed. Another solution is to improve turbine design from two perspectives: decreasing sound power without substantially decreasing electric power, and reducing annoyance by minimizing fluctuations in the sound. Part of any solution is to respect complainants and try to achieve a better balance between national benefits and local costs.

Oblivious of any research, residents had already noticed a discrepancy between predicted and real noise exposure. Opponents of wind farms have organized themselves in recent years in the Netherlands and elsewhere, and word had spread that noise exposure in some cases was worse than predicted. Though atmospheric stability and sometimes a malfunctioning turbine could explain this, most wind farm developers and their consultants relied on the old prediction methods. An energy firm's spokesman complained that each and every new project attracted complaints (from local groups) and called this "a new Dutch disease".¹ This is a very narrow view on the problem, denying the detrimental effects for residents. If their real concerns are denied it is not unreasonable for residents to oppose a new project, because practical experience shows that once the wind farm is there (or any other noise producer) and problems do arise, complaints will very probably not alter the situation for at least several years. Social scientists are familiar with such situations and suggest better strategies such as being honest and respectful, treating residents as equal partners, and not being arrogant: already in 1990 Wolsink mentioned this in a study on acceptance of wind energy and warned that it was wrong to label opposition as NIMBY (Not In My Back Yard) and refuse to recognize

¹ NRC Handelsblad, August 26 2005: "Verzet tegen windmolens succesvol" ("Opposition to wind mills successful")

legitimate problems [Wolsink 1990]. It is sad that most of the proponents still emanate a WARYDU attitude (We Are Right but You Don't Understand).

When real complaints are not addressed seriously, the "new Dutch disease" may well become an Australian, British, Chinese or any nation's disease. In the Netherlands assessment of wind turbine noise still is according to the old standard procedure (with one exception, see chapter VII), assuming a neutral atmosphere at all times, even though this has been admitted to be wrong for more than a year now.¹ Consultants apparently are afraid to be critical, perhaps because they don't want to jeopardize new assignments or because a change in assessment implies they were not correct before (they were not correct, but we were wrong collectively). Though most consultants claim to be impartial, the problem of 'not biting the hand that feeds' is more subtle, as I concluded in an earlier desk study on the quality of acoustic reports [Van den Berg 2000]. E.g., it involves authorities who do not question the position of paid experts, and a society hiding political decisions behind the demand for more research.

I hope other countries do not to follow the Dutch way: first denying the consistency and legitimacy of the complaints, then being late in addressing them and in the end finding this has created more opposition. It is evident that also in the UK there are (a few?) serious complaints from honest people that are not dealt with adequately. In at least some cases atmospheric stability again seems to offer an explanation for observations of unpleasant wind turbine noise by residents (see example in box on next page), but the matter has not been investigated correctly.

¹ In March 2004 I showed in an article in 'Geluid', a Dutch professional journal, how to deal with non-neutral atmospheric conditions within the existing legal procedures [Van den Berg 2004c]; in July 2004 the Ministry of Housing, Environment and Spatial Planning advised to investigate the 'wind climate' at new wind farm locations (letter on "Beoordeling geluidmetingen Natuurkundewinkel RUG bij De Leth, gem. Bellingwedde" to Parliament by State Secretary van Geel, June 21, 2004); in the 2005 Annual report of BLOW, a union of local, provincial and national authorities to promote wind energy development, it is recognized that the effect of wind shear still should be addressed, but no action is announced (Annual report BLOW 2005, January 2006).

NOISE FROM WINDFARM MAKING LIFE A MISERY

A recent settler in Caithness claimed yesterday his life is being blighted by ghostly noises from his new neighbours, the county's first large-scale windfarm. (.....) Mr Bellamy said: "The problem is particularly bad at night when I try to get to sleep and there's a strong wind coming from the direction of the turbines. They just keep on droning on. It's a wook wook type of sound, a ghostly sort of noise. It's like torture and would drive anyone mad."

Mr Bellamy believes the noise is being transmitted through the ground since it seems to intensify when he lies down. He said he has got nowhere with complaints to the wind company and environmental health officers. "I feel I'm just getting fobbed off and can't get anyone to treat me seriously," he said. Mr Bellamy has been asked to take noise readings every 10 minutes during problem times, something he claims is unrealistic to expect him to do. He said the company's project manager Stuart Quinton-Tulloch said they could not act until it had proof of unacceptable noise levels. Mr Bellamy said: "I'm not the moaning type and I have no problem with the look of the windmills. I'm not anti-windfarm. It's just the noise which is obviously not going to go away." (.....)

Highland Council's principal environment officer Tom Foy who has been dealing with Mr Bellamy's complaint was unavailable for comment. His colleague David Proudfoot said he was aware of noise complaints about the Causewaymire turbines being lodged by two other residents, but said he had gone out several times and found no evidence to support the concerns.

Part of an article in *Press and Journal of Aberdeen*, 25 May 2005

Thinking that this could perhaps be solved by the Sustainable Development Commission (SDC), the UK government's 'independent advisory body on sustainable development'. I wrote to the SDC about remarks on wind turbine noise in their report "Wind power in the UK" [SDC 2005], which was in my opinion too positive and somewhat overly optimistic regarding wind turbine noise. The SDC replied, on authority of its (unknown) consultants, that they had no detailed knowledge of atmospheric conditions in the UK but still thought an impulsive character of the noise 'likely to be very rare'. After I presented some examples the SDC preferred to close the discussion.

The situation in the Netherlands is not very different. In the latest annual report of the body of national, provincial and local authorities responsible for wind energy development it is acknowledged that the problem of underrated noise has justly been brought to the policy agenda.¹ Nevertheless, no activity is undertaken to remedy this.

1.4 Large scale benefits and small scale impact

Though wind turbine noise is the main topic of this book, it is not the main problem in wind power development. Visual impact is usually considered the most important and most discussed local or regional effect. It is often presented as a matter of individual taste, though there are some common factors in 'public taste'. One such factor is the perceived contrast of a wind turbine (farm) and its environment: a higher contrast will have more impact, either in a positive or negative way. A peculiarity of turbines is that the rotational movement makes them more conspicuous and thus enhances visual impact. This common notion suggests that wind turbines in a built up area will have less impact relative to a remote natural area (though this may be overruled by the number of people perceiving the impact).

A second factor is attitude: e.g. farmers usually have a different attitude to the countryside than 'city folk' have, and hence they differ in judgments on the appropriateness of a building, construction or activity in the

¹ Jaarverslag BLOW (Bestuursvereenkomst Landelijke Ontwikkeling Windenergie). 2005 (Annual report BLOW 2005: in Dutch), January 2006

countryside. It is predictable that when residents have a positive association with a neighbouring wind farm they will experience less annoyance from the visual impact. For a wind turbine owner the sound of each blade passing means another half kWh is generated¹ and is perhaps associated with the sound of coins falling into his lap, a lullaby. The very same rhythm, like the proverbial leaking faucet tap, might prevent his neighbour from falling asleep.

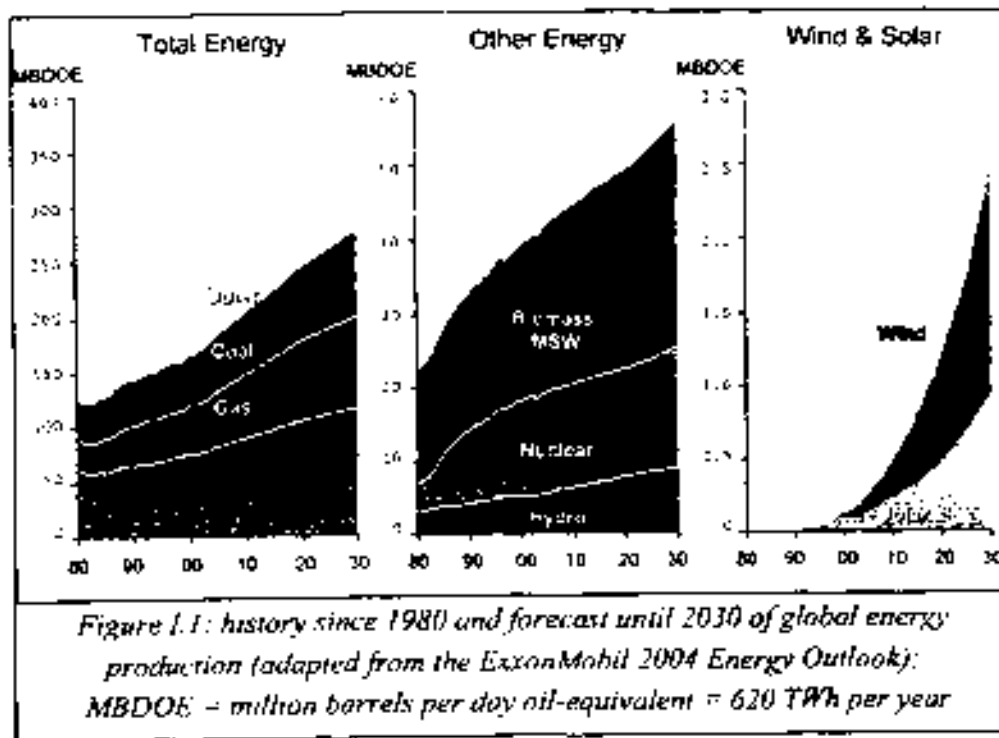

Other issues have gained attention in the public discussion, such as the modest contribution of wind energy to total energy consumption and the problematic variability of wind power. This is not the place to discuss these issues, except that they partially depend on a person's world view and expectations of the future. But I would like to show my personal position here. I find it astounding to realize that *all* wind turbine energy generated in the Netherlands in one year (2004) is equal to two months' *growth* of the total Dutch energy consumption. And even though wind turbine energy now provides about 2% of the total Dutch electricity consumption, this is only 0.2% of our total energy consumption.² This is also true on a global scale as is clear from figure 1.1: wind power is now negligible and expected to supply 0.5% in 2030.

Despite the disappointingly low percentages I still think that wind energy need not be insignificant. In my view the problem is rather that we use such vast amounts of energy and keep on using ever more, which is a problem that no source, including wind power, can solve. Society will need to find a stand in the variety of opinions that have been brought forward since the 1970's. In a recent newspaper discussion about the liberalization of the energy market an opinion maker stated: "It is now generally appreciated that the end of the rich era of energy approaches rapidly, and the competition has begun for the last stocks", whilst his opponent the Minister of Economic Affairs wrote: "The lights must be kept burning, the

¹ when the turbine generates 2 MW at 20 rpm

² the percentages are based on data from Statistics Netherlands (Centraal Bureau voor Statistiek) for the Netherlands for the year 2004: wind energy production: 1.9 TWh; total electricity consumption: 108.5 TWh; total energy consumption: 919 TWh. Growth in total energy consumption in period 1995 - 2004: + 100 TWh or 1.7 TWh per two months. Growth in total electricity consumption 1995 - 2004: +23 TWh or 2.3 TWh per year.

gas must keep flowing".¹ I do not agree with the Minister: I think that a limited resource should require limited consumption, even at the cost of some discomfort to our spoiled society. If we can curb our Joule addiction, wind power may help us to produce part of the sustainable energy we need to satisfy basic needs.

Wind turbine noise is a problem that may grow due to neglect by wind energy proponents and thus it may be another reason for part of the public, with politicians following, to turn away from wind power. This problem can be solved when it is also addressed at the level of local impact; sustainability must also apply at the local level. Some technical possibilities for noise reduction are given in this book and more competent, hardware oriented people may come up with better solutions. In addition to this, the social side of the problems must not be neglected. In a recent study [Van As *et al* 2005] it was concluded that "growing public resistance

¹ NRC Handelsblad 8-11-2005, articles "Bezinning nodig over energiebeleid" ("Energy policy needs reflection" by W. van Dierent) and "Nieuw debat schept slechts onzekerheid" ("New debate only creates uncertainty" by Laurens Jan Brinkhorst); my translations

to onshore wind turbines" obstructs wind energy development in the Netherlands. According to the report this opposition is now the main bottle-neck: local communities and residents are faced with the disadvantages whilst others (proponents, society at large) reap the benefits. The report recommends that the former share in the benefits too.

1.5 *Microphone wind noise*

In contrast to the impact my wind turbine research has had in society, the same knowledge of atmospheric physics helped me solve a non-controversial problem of interest to only a few: what is the nature of the noise that wind creates in a microphone? It occurred to me that if atmospheric turbulence was the cause, then one must be able to calculate the level of this noise. I was delighted when I found out how well theoretical considerations fitted hitherto only vaguely understood measurement results. Eureka!, such is the joy of work in science.

Somewhat unexpectedly this second discovery turns out to be related to wind turbine sound, which is why it is in this book. Originally it was considered difficult to measure wind turbine sound, because the strong winds that were supposed to cause high wind turbine sound levels, also were believed to be responsible for a lot of microphone wind noise. Solutions to this problem were either to put the microphone out of the wind on the ground or use several microphones and decrease microphone noise by averaging over all microphone signals. A new solution offered in this book is to take measurements in a stable atmosphere where near-ground wind velocity is so low that microphone noise is far less of a problem. One can measure sound at distances from a wind farm most researchers would not now believe to be possible.

The relationship is even stronger. In some countries the level of ambient background sound determines (part of) the limit imposed on sound exposure. To measure the level of this background sound the microphone must be put up in a place where residents stay outdoors, also in stronger winds. In this case it is important to discriminate between real ambient

sound and the noise that wind produces in the microphone. With the calculation methods in this book it is now possible to do so.

1.6 Research aims

The issues raised above concerning wind turbine noise and its relationship to altitude dependent wind velocity led to the following issues to be investigated:

- ◆ what is the influence of atmospheric stability on the speed and sound power of a wind turbine?
- ◆ what is the influence of atmospheric stability on the character of wind turbine sound?
- ◆ how widespread is the impact of atmospheric stability on wind turbine performance: is it relevant for new wind turbine projects?; how can noise prediction take this stability into account?
- ◆ what can be done to deal with the resultant higher impact of wind turbine sound?

Apart from these directly wind turbine related issues, a final aim was to address a measurement problem:

- ◆ how does wind on a microphone affect the measurement of the ambient sound level?

1.7 Text outline and original work

This book gives an overview of results of the wind turbine noise research that has been presented in the international arena in the last few years, as well as some opinions on this topic in the Introduction and Epilogue. Most of the text in this book has been published in scientific journals or presented at conferences. However, the texts have been adapted somewhat so as to form a continuous story without too much overlap. Other changes have been listed below.

- ◆ *Chapter II* is a reflection on some problems I encountered in doing research and presenting the results, most of it concerning wind turbine noise, but set against a more general background. It corresponds to a

paper presented at Euronoise 2003 [Van den Berg 2003], but some overlap with later chapters is taken out and some new information concerning the variation of wind turbine sound has been added (last paragraph in II.2). The remaining text has been edited slightly.

- *Chapter III* gives some numbers on wind energy development in the European Union, as well as an introduction on atmospheric wind gradients and the origins of aerodynamic wind turbine sound. It corresponds to sections of two published papers [Van den Berg 2004a and 2005a] to which remarks on the local wind speed at the turbine blade (section III.3) and on the spectrum of thickness sound (footnote in III.4) has been added. Also a description of sound and effects as given by a residential group with practical experience is added (box at end of chapter) and a remark on constant speed and variable speed wind turbines (in III.4).
- *Chapter IV* corresponds to my first paper on this topic [Van den Berg 2004a] on measurements at the Rhede wind farm. The section on Impulsive Sound has been taken out here and transferred to the next chapter. A new section (IV.10) has been added describing previously unpublished measurements at the Rhede wind farm as well as a comparison with calculated sound levels. Chapter IV demonstrates the fact that sound levels due to wind turbines have been systematically underestimated because hub height wind velocities were not correctly predicted. This effect is becoming more important for modern, tall wind turbines particularly when the atmosphere is 'non standard' (i.e. diverging from neutrality).
- In *chapter V* a second effect of atmospheric stability is investigated. Not only has the sound level been underestimated, but also the effect on the sound character: when the atmosphere turns stable, a more pronounced beating sound evolves. Most of the data are from the Rhede wind farm, complemented by data from a smaller single turbine elsewhere and theoretical calculations. In a section on the perception of fluctuating sound, it is explained how an apparently weak sound level variation can indeed turn into audibly pronounced beating. This chapter corresponds to a published paper [Van den Berg 2005a], but the section on interaction of several turbines (V.2.4) has been

combined with the corresponding section of the first paper [Van den Berg 2004a]. In this chapter the fact that wind velocity in the rotor is not equal to the free wind velocity, which was neglected in the paper, has been taken into account.

- ◆ In *chapter VI* data on atmospheric stability and wind statistics are presented. The raw data are from a location in the mid west of the Netherlands and have been provided by the KNMI. The analysis and application to a reference wind turbine help us to understand the behaviour of wind turbines and, together with research results from other countries, show that the atmospheric conditions found at the Rhede wind farm certainly were no exception. This chapter is the text of a paper presented at the WindTurbineNoise2005 conference [Van den Berg 2005b], with some results from other presentations at that conference added (in section VI.6).
- ◆ In *chapter VII* some possibilities are discussed to cope with the effects of atmospheric stability on wind turbine noise, either by controlling wind turbine performance or by new designs. In part this is derived from a project in the town of Houten where the town council wants to permit a wind farm, taking into account the effect on residents, especially at night. This chapter is a somewhat expanded version (a concluding section has been added) of a second paper presented at the WindTurbineNoise2005 conference [Van den Berg 2005c].
- ◆ In *chapter VIII* a new topic is introduced: how does wind affect sound from a microphone? It shows that atmospheric turbulence, closely related to -again- atmospheric stability, is the main cause of wind induced microphone noise. The chapter corresponds to a published article [Van den Berg 2006].
- ◆ In *Chapter IX* all results are summarized. Based on these general conclusions recommendations are given for a fresh look at wind turbine noise.
- ◆ Finally, in *chapter X*, some thoughts are given to conclude the text. After that the appendices give additional information.

II ACOUSTICAL PRACTICE AND SOUND RESEARCH

II.1. Different points of view

In 2001 the German wind farm Rhede was put into operation close to the Dutch border. Local authorities as well as residents at the Dutch side had opposed the construction of the 17 wind turbines because of the effects on landscape and environment: with 98 m hub height the 1.8 MW turbines would dominate the skyline of the early 20th century village of Bellingwolde and introduce noise in the quiet area.

With the turbines in operation, residents at 500 m and more from the wind farm found the noise (and intermittent or flicker shadow, which will not be dealt with here) worse than they had expected. The wind farm operator declined to take measures as acoustic reports showed that German as well as Dutch noise limits were not exceeded. When the residents brought the case to a German court, they failed on procedural grounds. For a Dutch court they had to produce arguments that could only be provided by experts.

Science Shops are specifically intended to help non-profit groups by doing research on their behalf. For the Science Shop for Physics in Groningen noise problems constitute the majority of problems that citizens, as a group or individually, come up with. Although the aim of our research is the same as for acoustic consultants –to quantify sound levels relevant for annoyance- the customers are different: consultants mostly work for the party responsible for the sound production, whereas the Science Shop mostly works for the party that is affected by the sound. This may lead to different research questions. In the case of wind farm Rhede a consultancy will check the sound production of the turbines and check compliance of the calculated sound immission level with relevant limits. However, the Science Shop, taking the strong reaction from the residents as a starting point, wanted to check whether the real sound immission agrees with the

calculated one and whether sound character could explain extra annoyance.

In the Dutch professional journal 'Geluid' it was shown, on the basis of 30 acoustic reports, that acoustic consultants tend to rely too much on information from their customers, even when they had reason to be critical about it [Van den Berg 2000]. As consultants' customers are usually noise producers and authorities, the point of view of those that are affected by noise is not usually very prominent. This book shows that for wind turbines a similar case can be made.

11.2 Results from our wind turbine research

The results of the investigation of the sound from the wind farm Rhede are given in the next chapters. Here the results will be dealt with briefly. The main cause for the high sound level perceived by residents is the fact that wind velocities at night can, at 100 m height, be substantially higher than expected. As a consequence a wind turbine produces more sound. As measured immission levels near the wind farm Rhede show, the discrepancy may be very large: sound levels are up to 15 dB higher than expected at 400 m from the wind farm. The important point is not so much that the maximum measured sound level is higher than the maximum expected sound level (it was, around +2 dB, but this was not an effect of the wind velocity profile). The point is that this maximum does not only occur at high wind velocities as expected, accompanied by high wind induced ambient sound levels, but already at relatively low wind velocities (4 m/s at 10 m height) when there is little wind at the surface and therefore little wind induced background sound. Thus, the discrepancy of 15 dB occurs at quiet nights, but yet with wind turbines at almost maximum power. This situation occurs quite frequently.

A second effect that adds to the sound annoyance is that the sound has an impulsive character. The primary factor for this appeared to be the well known swishing sound one hears close to a turbine. For a single turbine these 1 – 2 dB broad band sound pressure fluctuations would not classify as impulsive, but at night this swish seems to evolve into a less gentle thumping. Also, when several turbines operate nearly synchronously the

pulses may occur in phase increasing pulse strength further. At some distance from the wind farm this sound characteristic, described as thumping or beating, can be very pronounced though in the wind farm, close to a turbine, we never heard this impulsiveness.

Indeed, close to a turbine it seems that most sound is coming from the downgoing blade, not when it passes the tower. One has to be careful in estimating blade position, as an observer at, say, 100 m from the foot of the tower is 140 m from a 100 m hub and therefore hears the sound from a blade approximately half a second after it was produced, in which time a blade may have rotated over some 30°. At the Berlin WindTurbineNoise conference Oerlemans [2005] explained this phenomenon: when the blade comes down and heads towards the observer, the observer is at an angle to the blade where most sound is radiated (see remark on directivity just below equation B.5 in Appendix B). On top of that the high tip velocity (70 m/s) causes a Doppler amplification. Both effects increase the sound level for our observer. However, this observation cannot be used for a distant turbine as in that case the observer sees the rotor sideways. Then the change due to the directivity of the sound is small, and also the Doppler effect is nil as the change in the velocity component towards the observer is negligible.

11.3 Early warnings of noisy wind turbines?

One may wonder why the strong effect of the nightly wind profile or the thumping was not noticed before. In the 1998 publication IEC 16400 only the neutral logarithmic wind profile is used [IEC, 1998]. As recent as 2002 it was stated that wind turbine sound is not impulsive [Kerkers *et al* 2002], which was concluded from assumed, not from measured sound level variations.

There have been some warnings, though. In 1998 Rudolphi concluded from measurements that wind velocity at 10 m height is not a good measure for the sound level: at night the (58 m hub height) turbine sound level was 5 dB higher than expected [Rudolphi 1998]. This conclusion was not followed by more thorough investigation. Since several years residential groups in the Netherlands and abroad complained about

annoying turbine sound at distances where they are not even expected to be able to hear the sound. Recently Pedersen *et al* [2003, 2004] found that annoyance was relatively high at calculated maximum sound immission levels below 40 dB(A) where one would not expect strong annoyance. As wind turbines become taller, the discrepancy between real and expected levels grows and as more tall wind turbines are constructed complaints may become more widespread. In the Netherlands residents near the German border were the first Dutch to be acquainted with turbines of 100 m hub heights.

It may be that earlier discrepancies between real and projected sound immission were not sufficient to evoke strong community reactions and that only recently turbines have become so tall that the discrepancy now is intolerable.

There are other reasons that early warnings perhaps did not make much impression. One is that sound emission measurements are usually done in daytime. It is hard to imagine the sound would be very different at night time, so (almost) no one did. Until some years ago, I myself could not imagine how people could hear wind turbines 2 km away when at 300 to 400 m distance the (calculated) immission level was, for a given wind velocity, already equal to the ambient background sound level (L_{95}). But it proved I had not listened in a relevant period: an atmospherically stable night.

What is probably also a reason is the rather common attitude that 'there are always people complaining'. Complaints are a normal feature, not as such a reason to re-investigate. Indeed Dutch noise policy is not to prevent any noise annoyance, but to limit it to acceptable proportions. Added to this is a rather general conviction of Dutch authorities and consultants that routine noise assessment in compliance with legal standards must yield correct results. If measurements are performed it is to check actual emission levels -usually in normal working hours, so in daytime. It is quite unusual to compare the calculated sound immission from a wind turbine (farm) with measured immission levels (so unusual that it is likely that we were the first to do so).

A third reason may be partiality to the outcome of the results. Wind turbine operators are not keen on spending money that may show that sound levels do not comply with legal standards. And if, as expected, they do comply, the money is effectively wasted. Apart from this, we have the experience that at least some organisations that advocate wind energy are not interested in finding out why residents oppose wind farms.

II.4 The use of standard procedures

Although our objective was to measure immission sound levels, we also wanted to understand what was going on: if levels were higher than expected, was that because emission was higher or attenuation less? Could there be focussing or interference? We therefore also measured sound emission as a function of rotational speed of the variable speed turbines. An interesting point that came up with the emission measurement was that compliance with the recommended standard [Ljunggren 1997 or IEC 1998] was impossible. As the farm operator withdrew the co-operation that was previously agreed upon, we had to measure emission levels with the full wind farm in operation, as we obviously did not have the means to stop all turbines except the one to be measured, as the standard prescribes. To measure ambient background sound level, even the last turbine should be stopped.

According to the recommended standard the sound emission should be measured within 20% of the distance to the turbine equal to hub height + blade length. However, to prevent interference from the sound from other turbines the measurement location had to be chosen closer to the turbine.

The primary check on the correctness of the distance (i.e. not too close to other turbines) was by listening: the closest turbine should be the dominant source. If not, no measurement was done, and usually a measurement near another turbine was possible. Afterwards we were able to perform a second check by comparing the measured sound immission of the wind farm at a distance of 400 m with the level calculated with a sound propagation model with the measured emission level of all (identical) turbines as input. The calculated difference between a single turbine sound power level and the immission level was 58.0 dB (assuming a constant spectrum this is independent from the power level itself). The measured average difference

was 57.9 dB, with a maximum deviation of individual measurement points of 1.0 dB. So our measurements proved to be quite accurate, deviating only 0.1 ± 1.0 dB from the expected value! In fact, from our measurements one may conclude that, to determine turbine sound power level, it is easier and cheaper to determine total sound emission by measurements at some distance from a wind farm than measuring separate turbines. The wind induced ambient sound, that easily spoils daytime measurements, is not an important disturbance in many nights!

Using a 1 m diameter round hard board, again to comply with the standard, was quite impractical and sometimes impossible. *E.g.* at one place potato plants would have to be cleared away, at another place one would have to create a flat area in clumps of grass in a nature reserve, both unnecessarily. Instead of the large board we used the side (30-44 cm²) of a plastic sound meter case. We convinced ourselves that (in this case) this was still a good procedure by comparing at one location sound levels measured on the case on soft ground with sound levels measured on a smooth tarmac road surface a few meters away, both at the same distance to the turbine as in the other measurements: there was no difference.

Whether a turbine produces impulsive sound is usually determined by listening to and measuring the sound near a single turbine (along with measurements to determine sound power and spectral distribution). In the Netherlands impulsivity is judged subjectively (by ear), not by a technical procedure as in Germany, though judgement can be supported with a sound registration showing the pulses. Interestingly, in Dutch practice only an acoustician's ear seems reliable, though even their opinions may disagree. From our measurements the impulsive character can be explained by the wind profile and the interaction of the sound of several turbines. Even at a time the impulsive character can be heard near residents' dwellings, it cannot clearly be heard close to the turbines in the wind farm (as explained in section H.2). So here also there was need to do measurements where people are actually annoyed, and not to rely on source measurements only, certainly not from a single turbine.

When noise disputes are brought to court, it is clearly advantageous to have objective procedures and standards to assure that the technical quality, which can hardly be judged by non experts, is sufficient and therefore the results are reliable. In the case made here however, a standard may be non-applicable for valid reasons. Nonetheless, the emission measurements have been contested on procedural grounds (*viz.* we have not complied to the standard [Kerkers 2003]), even though the immission sound levels were the primary research targets and we did not really need the sound emission measurement results (which, however, proved very accurate).

The tendency to put all noise assessment into technical standard procedures has the disadvantage that when there is a flaw in a legally enforced standard, still the standard is followed, not reality. It is hardly possible for non-experts, such as residents, to bring other arguments to court. They, the annoyed, will have to hire an expert to objectify their annoyance. This is not something every citizen can afford.

11.5 Modelling versus measurements

Being able to calculate sound levels from physical models is a huge advantage over having to do measurements (if that, indeed, is possible) especially as in practical situations conditions keep changing and other sounds disturb the measurements. Because of its obvious advantages models have become far more important for noise assessment than measurements. In the Netherlands usually sound emission measurements are carried out close to a source to determine sound power levels. Then, with the sound power level, the immission level is calculated, usually on façades of residences close to the sound source. It is not common to measure immission levels in the Netherlands: in some cases (e.g. railway, aircraft noise) there is not even a measurement method (legally) available to check calculated levels.

However, a physical model is never the same as reality. As will be shown in this book, the widely used standard to quantify sound emission from wind turbines is implicitly based on a specific wind profile. This profile is

not correct at night, although the night is the critical period for wind turbine noise assessment.

Even a perfect physical model will not reproduce reality if input values are not according to reality. An example is to apply sound power levels from new sources (cars, road surfaces, aeroplanes, mopeds, vacuum cleaners, etc.), maybe acquired in a specific test environment, to real life situations and conditions. Another example is a wind farm south of the Rhede wind farm where a turbine produced a clearly audible and measurable tonal sound, probably caused by damage on a blade. It is very hard for residents to convince the operator and authorities of this annoying fact, partly because most experts say that modern wind turbines do not produce tonal sound.

Incorrect models and incorrect input may well occur together and be difficult to separate. It is important that calculation models are checked for correctness when they are used in new applications. Situations where (strong) complaints arise may indicate just those cases where models do not cover reality.

11.6 Conclusion

In modelling wind turbine sound very relevant atmospheric behaviour has been 'overlooked'. As a consequence, at low surface wind velocities such as often occur at night, wind turbine noise immission levels may be much higher than expected. The discrepancy between real and modelled noise levels is greater for tall wind turbines. International models used to assess wind turbine noise on dwellings should be revised for this atmospheric effect, at least by giving less attention to the 'standard' neutral atmosphere.

A discrepancy between noise forecasts and real noise perception, as a result of limited or even defective models, cannot always be avoided, even not in principle. However, its consequences can be minimised if immission levels are measured at relevant times and places. This relevancy is also determined by observations of those affected. It should always be possible to check noise forecasts by measurement.

For wind turbine noise (and other noise sources) standard measurement procedures require co-operation of the operator to be able to check emission sound levels. This introduces an element of partiality to the advantage of the noise producer. This is also generally a weak point in noise assessment: the source of information is usually the noise producer. Hence there should always be a procedure to determine noise exposure independently of the noise producer.

Standard technical procedures have the benefit of providing quality assurance: when research has been conducted in compliance with a standard procedure lay persons should be able to rely on the results. It may however also have a distinct disadvantage for lay people opposing a noise source: when an assessment does not comply with a standard procedure it is not accepted in court, regardless of the content of the claim. A consequence is they have to depend on legal as well as acoustical expertise. If citizens are forced to use expert knowledge, one may argue that they should be given access to that knowledge. An important obstacle is the cost of that access.

III BASIC FACTS: wind power and the origins of modern wind turbine sound

III.1 Wind energy in the EU

Modern onshore wind turbines have peak electric power outputs up to 3 MW and tower heights of 80 to 100 meters. In 2003, 75% of the global wind power peak electric output of 40 GW was installed in the European Union. The original European target for 2010 was 40 GW, but the European Wind Energy Association have already set a new target for 2010 of 75 GW, of which 10 GW is projected off-shore, while others have forecasted a peak output of 120 GW for that year [EWEA 2004]. Whether this growth will actually occur is uncertain; with the proportional increase of wind energy in total electric power the difficulties and costs of integrating large scale windpower with respect to grid capacity and stability, reserve capacity and CO₂ emission reductions are becoming more prominent (see, e.g., E.ON 2004, ESB 2004)). However, further expansion of wind energy is to be expected, and as a result of this (predominantly on-shore) growth an increasing number of people may face the prospect of living near wind farms, and have reason to inquire and perhaps be worried about their environmental impact. Visual intrusion, intermittent reflections on the turbine blades, as well as intermittent shadows (caused when the rotating blades pass between the viewer and the sun), and sound, are usually considered potentially negative impacts.

III.2 Wind profiles and atmospheric stability

Atmospheric stability has a profound effect on the vertical wind profile and on atmospheric turbulence strength. Stability is determined by the net heat flux to the ground, which is a sum of incoming solar and outgoing thermal radiation, and of latent and sensible heat exchanged with the air and the subsoil. When incoming radiation dominates (clear summer days) air is heated from below and rises: the atmosphere is unstable. Thus, thermal turbulence implies vertical air movements, preventing large

variations in the vertical wind velocity gradient (*i.e.* the change in time averaged wind velocity with height). When outgoing radiation dominates (clear nights) air is cooled from below; air density will increase closer to the ground, leading to a stable configuration where vertical movements are damped. The 'decoupling' of horizontal layers of air allows a higher vertical wind velocity gradient. A neutral state occurs when thermal effects are less significant, which is under heavy clouding and/or in strong winds.

Wind velocity at altitude h_2 can be deduced from wind velocity at altitude h_1 with a simple power law function:

$$V_{h_2}/V_{h_1} = (h_2/h_1)^m \quad (\text{III.1})$$

Equation III.1 is an engineering formula used to express the degree of stability in a single number (the shear exponent m), but has no physical basis. The relation is suitable where h is at least several times the roughness height (a height related to the height of vegetation or obstacles on the ground). Also, at high altitudes the wind profile will not follow (III.1), as eventually a more or less constant wind velocity (the geostrophic wind) will be attained. At higher altitudes in a stable atmosphere there may be a decrease in wind velocity when a nocturnal 'jet' develops. The maximum in this jet is caused by a transfer of kinetic energy from the near-ground air that decouples from higher air masses as large, thermally induced eddies vanish because of ground cooling. In fact, reversal of the usual near-ground diurnal pattern of low wind velocities at night and higher wind velocities in daytime is a common phenomenon at higher altitudes over land in clear nights as will be shown further below (Chapter VI). Over large bodies of water the phenomenon may be seasonal as atmospheric stability occurs more often when the water is relatively cold (winter, spring). This may also be accompanied by a maximum in wind velocity at a higher altitude [Smedman *et al* 1996].

In flat terrain the shear exponent m has a value of 0.1 and more. For a neutral atmosphere m has a value of approximately 1/7. In an unstable atmosphere –occurring in daytime– thermal effects caused by ground heating are dominant. Then m has a lower value, down to approximately

0.1. In a stable atmosphere vertical movements are damped because of ground cooling and m has a higher value. One would eventually expect a parabolic wind profile, as is found in laminar flow, corresponding to a value of m of $0.7 = \sqrt{1/2}$. Our measurements near the Rhede wind farm yielded values of m up to 0.6. A sample (averages over 0:00–0:30 GMT of each first night of the month in 1973) from data from a 200 m high tower in flat, agricultural land [Van Ulden *et al* 1976] shows that the theoretical value is indeed reached: in ten out of the twelve samples there was a temperature inversion in the lower 120 m, indicating atmospheric stability. In six samples the temperature increased with more than 1 °C from 10 to 120 m height and the exponent m (calculated from (III.1): $m = \log(V_{80}/V_{10})/\log(8)$) was 0.43, 0.44, 0.55, 0.58, 0.67 and 0.72. More data from this site (Cabauw) and other areas will be presented in chapter VI.

A physical model to calculate wind velocity V_h at height h is ([Garrat 1992], p. 53):

$$V_h = (u_* / \kappa) \{ \ln(h/z_0) - \Psi \} \quad (\text{III.2})$$

where $\kappa = 0.4$ is von Karman's constant, z_0 is roughness height and u_* is friction velocity, defined by $u_*^2 = \sqrt{\langle uw \rangle^2 + \langle vw \rangle^2} = \tau/\rho$, where τ equals the momentum flux due to turbulent friction across a horizontal plane, ρ is air density and u , v and w are the time-varying components of in-wind, cross-wind and vertical wind velocity, with $\langle x \rangle$ the time average of x . The stability function $\Psi = \Psi(\zeta)$ (with $\zeta = h/L$) corrects for atmospheric stability. Here Monin-Obukhov length L is an important length scale for stability and can be thought of as the height above which thermal turbulence dominates over friction turbulence; the atmosphere at heights $0 < h < L$ (if L is positive and not very large) is the stable boundary layer. The following approximations for Ψ , mentioned in many text books on atmospheric physics (e.g. [Garrat 1992]), are used:

- in a stable atmosphere ($L > 0$) $\Psi(\zeta) = -5\zeta < 0$.
- in a neutral atmosphere ($|L|$ large $\rightarrow 1/L \approx 0$) $\Psi(0) = 0$.
- in an unstable atmosphere ($L < 0$) $\Psi(\zeta) = 2 \cdot \ln[(1+x)/2] + \ln[(1+x^2)/2] - 2/\tan(x) + \pi/2 > 0$, where $x = (1-16\zeta)^{1/4}$.

For $\Psi = 0$ equation (III.2) reduces to $V_{h,\log} = (u_* / \kappa) \ln(h/z_0)$, the widely used logarithmic wind profile. With this profile the ratio of wind velocities at two heights can be written as:

$$V_{h_2,\log} / V_{h_1} = \log(h_2/z_0) / \log(h_1/z_0) \quad (\text{III.3})$$

For a roughness length of $z_0 = 2$ cm (pasture) and $m = 0.14$, the wind profiles according to equations III.1 and III.3 coincide within 2% for $h < 100$ m. In figure III.1 wind profiles are given as measured by Holtstag [1984], as well as wind profiles according to formulae (III.1) and (III.3).

Formula III.3 is an approximation of the wind profile in the turbulent boundary layer of a neutral atmosphere, when the air is mixed by turbulence resulting

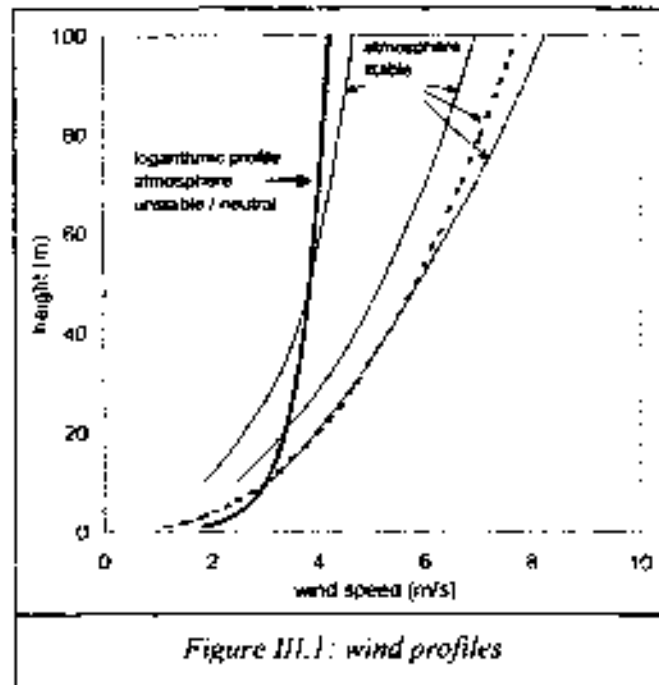

Figure III.1: wind profiles

from friction with the surface of the earth. In daytime thermal turbulence is added, especially when there is strong insolation. At night time a neutral atmosphere, characterized by the adiabatic temperature gradient of -1 °C per 100 m, occurs under heavy clouding and/or at relatively high wind velocities. When there is some clear sky and in the absence of strong winds the atmosphere becomes stable because of radiative cooling of the surface; the wind profile changes and can no longer be adequately described by (III.3). The effect of the change to a stable atmosphere is that, relative to a given wind velocity at 10 m height in daytime, at night there is a higher wind velocity at hub height and thus a higher turbine sound power level; also there is a lower wind velocity below 10 m and thus less wind-induced sound in vegetation.

With regard to wind *power* some attention is being paid to stability effects and thus to other wind profile models such as the diabatic wind velocity model (III.2) [see, e.g., Archer *et al* 2003, Baidya Roy *et al* 2004, Pérez *et al* 2004, Smedman *et al* 1996, Smith *et al* 2002]. In relation to wind turbine *sound*, much less attention has been given to atmospheric stability (see section II.3).

Stability can also be categorized in Pasquill classes that depend on observations of wind velocity and cloud cover (see, e.g., [LLNL 2004]). They are usually referred to as classes A (very unstable) through F (very stable). In a German guideline [TA-Luft 1986] a closely related classification is given (again closely related to the international Turner classification [Kühner 1998]). An overview of stability classes with the appropriate value of m is given in table III.1.

Table III.1: stability classes and shear exponent m

Pasquill class	name	comparable stability class [TA-Luft 1986]	m
A	very unstable	V	0.09
B	moderately unstable	IV	0.20
C	neutral	IV2	0.22
D	slightly stable	IV1	0.28
E	moderately stable	II	0.37
F	(very) stable	I	0.41

According to long-term data from Eelde and Leeuwarden [KNMI 1972], two meteorological measurement sites of the KNMI (Royal Netherlands Meteorological Institute) in the northern part of the Netherlands, a stable atmosphere (Pasquill classes E and F) at night occurs for a considerable proportion of night time: 34% and 32% respectively.

From formula (III.3) the ratio of wind velocities at hub height (98 m) and reference height, over land with low vegetation ($z_0 = 3$ cm), is $f_{log} = V_{98}/V_{10} = 1.4$. According to formula (III.1) and table III.1 this ratio would

be $f_{\text{unstable}} = 1.2 \approx 0.85 \cdot f_{\text{log}}$ in a very unstable atmosphere and $f_{\text{stable}} = 2.5 = 1.8 \cdot f_{\text{log}}$ in a (very) stable atmosphere.

The shear exponent m can be determined from the measured ratio of wind velocities at two heights (V_{h2}/V_{h1}) using equation III.1:

$$m_{h1,h2} = \ln(V_{h2}/V_{h1})/\ln(h_2/h_1) \quad (\text{III.4})$$

III.3 Air flow on the blade

As is the case for aircraft wings, the air flow around a wind turbine blade generates lift. An air foil performs best when lift is maximised and drag (flow resistance) is minimised. Both are determined by the angle of attack: the angle (α) between the incoming flow and the blade chord (line between front and rear edge; see figure III.2). The optimum angle of attack for turbine blades is usually between 0 and 4°, depending on the blade profile.

The local wind at the blade is not the unobstructed wind velocity. The rotor extracts energy from the air at the cost of the kinetic energy of the wind. The velocity of the air passing through the rotor is thus reduced to $V_b = (1 - a)V_h$, where a is the induction factor. The highest efficiency of a wind turbine is reached at the Betz limit: at this theoretical limit the induction factor is $1/3$ and the efficiency is $16/27$ ($\approx 60\%$) [Hansen 2000]. The wind velocity at the blade is thus:

$$V_b = V_h \cdot 2/3 \quad (\text{III.5})$$

III.4 Main sources of wind turbine sound

There are many publications on the nature and power of turbine sound: original studies [e.g. Lawson 1985, Grosveld 1985] and reviews [e.g. Hubbard *et al* 2004, Wagner *et al* 1996]. A short introduction on wind aeroacoustics will be given to elucidate the most important sound producing mechanisms

If an air flow is smooth around a (streamlined) body, it will generate very little sound. For high velocities and/or over longer lengths the flow in the boundary layer between the body and the main flow becomes turbulent. The rapid turbulent velocity changes at the surface cause sound with frequencies related to the rate of the velocity changes. The turbulent boundary layer at the downstream end of an airfoil produces *trailing edge sound*, which is the dominant audible sound from modern turbines. When the angle of attack increases from its optimal value the turbulent boundary layer on the suction (low pressure) side grows in thickness, thereby decreasing power performance and increasing sound level. For high angles of attack this eventually leads to stall, that is: a dramatic increase of drag on the blades. Apart from this turbulence inherent to an airfoil, the atmosphere itself is turbulent over a wide range of frequencies and sizes.

Figure III.3: 15 m blades for Altamont Pass, Ca (photo: Alex Haag)

Turbulence can be defined as changes over time and space in wind velocity and direction, resulting in velocity components normal to the airfoil varying with the turbulence frequency causing *in-flow turbulent sound*. Atmospheric turbulence energy has a maximum at a frequency that depends on altitude and on atmospheric stability. For wind turbine altitudes

this peak frequency is of an order of magnitude of once per minute (0.017 Hz). The associated eddy (whirl) scale is of the order of magnitude of several hundreds of meters [Petersen *et al* 1998] in an unstable atmosphere, less in a stable atmosphere. Eddy size and turbulence strength decrease at higher frequency, and vanish due to viscous friction when the eddies have reached a size of approximately one millimetre.¹

A third sound producing mechanism is the response of the blade to the change in lift when it passes the tower. The wind is slowed down by the tower which changes the angle of attack on the blade; as a result the lift and drag forces on the blade suddenly change. The resulting sideways movement of the blade causes *thickness sound* at the blade passing frequency and its harmonics.² Thickness sound is also mentioned as sound originating from the (free) rotating blade pushing the air sideways. However, the associated air movement is relatively smooth and is not a relevant source of sound.

A more thorough review of these three sound production mechanisms is given in appendix B, where frequency ranges and sound levels are quantified in so far as relevant for this book.

Sound originating from the generator or the transmission gear has decreased in level in the past decades and has become all but irrelevant if considering annoyance for residents.

To summarize, a modern wind turbine sound spectrum can be divided in (overlapping) regions corresponding to the three mechanisms mentioned:

¹ for more information on atmospheric turbulence: see chapter VII

² a thickness sound pulse has a length t_{pulse} with an order of magnitude of (tower diameter/tip speed \approx) 0,1 s, so its spectrum has a maximum at $1/t_{\text{pulse}} \approx 10$ Hz. The spectrum of a periodic series of Dirac pulses (unit energy 'spikes' with, here, a period of T_{blade}) is a series of spikes at frequencies n/T_{blade} ($n = 1, 2, 3, 4, \dots$). When periodic thickness sound is considered as a convolution of the single sound pulse with a series of Dirac pulses, the Fourier transform is the product of the transforms of both, that is: the product of the sound pulse spectrum centered at $1/t_{\text{pulse}}$ and spikes at n/T_{blade} . The result is a series of spikes with the single sound pulse spectrum as an envelope, determining each spike level. In practice $1/T_{\text{blade}}$ usually has a value of 4 to 8 Hz (see e.g. (Wagner 1996)) and the harmonic closest to this frequency carries most energy.

- High frequency: *trailing edge (TE) sound* is noise with a maximum level at 500–1000 Hz for the central octave band, decreasing with 11 dB for neighbouring octave bands and more for further octave bands.
- Low frequency: *in-flow turbulent sound* is broad band noise with a maximum level of approximately 10 Hz and a slope of 3–6 dB per octave.
- Infrasound frequency ($f < 30$ Hz): the *thickness sound* is tonal, the spectrum containing peaks at the blade passing frequency f_b and its harmonics.

As thickness sound is not relevant for direct perception, turbulent flow is the dominant cause of (audible) sound for modern wind turbines. It is broad band noise with no tonal components and only a little variation, known as blade swish. Trailing edge sound level is proportional to $50 \cdot \log M$ (see equation B.4 in appendix B), where M is the Mach number of the air impinging on the blade. TE sound level, the dominant audible sound source in a modern turbine, therefore increases steeply with blade speed and is highest at the high velocity blade tips. Writing Mach number at the blade tip as $M = V_{tip}/c$, wind turbine sound level strongly depends on blade tip speed V_{tip} :

$$L_{TE} \sim 50 \cdot \log(V_{tip}/c) \quad (III.6)$$

Swish, which is the variation in TE sound, thus also originates predominantly at the tips.

This book deals with modern variable speed turbines where the angle of attack is constant over a wide range of wind speeds. Keeping blade pitch (the angle between the blade chord and the rotor plane) constant, the rotational speed increases with wind speed usually up to a rated wind speed of some 14 m/s. At higher wind speeds the pitch angle is decreased at constant rotational speed to keep a constant angle of attack until for safety reasons the rotor is stopped. The effect on sound production is that first the sound power level increases up to the rated wind speed, then remains almost constant at higher wind speeds.

In a constant speed turbine the rotational speed has a fixed value, though usually a turbine then has two speeds to accommodate for low and high wind speeds. Here the blade pitch is set to optimize the angle of attack up to the rated power. Above rated power, a situation that will not occur very often, the pitch angle is kept constant, so the angle of attack increases with wind speed and the turbine becomes less efficient. The result is that the sound power at low speed is almost constant, then increases sharply at the change to the higher speed. After that it is again almost constant, increasing again above the rated power when the angle of attack drifts away from the optimum value.

Sound from downwind rotors, *i.e.* with the rotor downwind from the tower, was considered problematic as it was perceived as a pulsating sound (see appendix B). For modern upwind rotors this variation in sound level is weaker. It is not thought to be relevant for annoyance and considered to become less pronounced with increasing distance due to loss of the effect of directivity, due to relatively high absorption at swish frequencies, and because of the increased masking effect of background noise [ETSU 1996]. However, an increase in the level of the swishing sound related to increasing atmospheric stability has not been taken into account as yet. In this context the periodic change in angle of attack near the tower proves to be important, not in relation to thickness sound but as a modulation period.

So, what's the sound like...?

(.....) Our experience is that mechanical noise is insignificant compared to the aerodynamic noise, or 'blade thump' as we call it. At "our" windfarm the mechanical noise is usually only audible when within about 100 metres of the turbine, but the blade thump can be heard at distances of up to 1.5 Km away.

(...)

Some residents describe this noise as an old boot in a tumble dryer, others as a Whumph! Whumph! Whumph! Either way its not particularly loud at 1.5 km distance but closer than that and it can be extremely irritating when exposed to it for any period of time. Some residents have even resorted to stuffing chimney stacks with newspaper as the sound reverberates down the stack.

Because it is generally rhythmic, it's not the kind of noise that you can shut out of your mind, like, say, distant road noise - this is why we think the noise level stipulation on the planning conditions of such a windfarm development is woefully inadequate for protecting local residents from the noise effects of a windfarm.

All of us agree that the most disturbing aspect of the noise is the beat that we think is caused by the blades passing the tower of the turbine. As the rotational speed of the 3 bladed turbines is about 28 rpm "on full song" this results in a sound of about 84 beats per minute from each turbine.

The sound rises and falls in volume due to slight changes in wind direction but the end result for those in the affected area is a feeling of anxiety, and sometimes nausea, as the rate continually speeds and slows - we think that is maybe because this frequency of the pulses is close to the human heart rate and some residents feel that their own pulse rate is trying to match that of the turbines. (.....)

When does it strike?

The windfarm makes a noise all the time it is operating, however there are times when it becomes less of a nuisance.

When the wind is very strong, the background noise created by the wind whistling around trees etc. drowns out the noise of the turbines and the problem is reduced. (.....)

In this area we all agree that the worst conditions are when the wind is blowing lightly and the background noise is minimal. Under these conditions residents up to 1 kilometre have complained to the Environmental Health department about the drone from the turbines. Unfortunately these are just the sort of weather conditions that you would wish to be outside enjoying your garden. (...)

During the summer nights it is not possible for some residents, even as far away as 1000 metres, to sleep with the window open due to the blade thump. (.....)

Excerpts describing wind turbine sound and its effects, from a page of the website of MAIWAG (consulted December 3, 2003), a group of residents in three villages in the south of Cumbria (UK)

IV LOUD SOUNDS IN WEAK WINDS: effect of the wind profile on turbine sound level

IV.1 The Rhede wind farm

In Germany several wind turbine farms have been and are being established in sparsely populated areas near the Dutch border. One of these is the Rhede wind farm in northwestern Germany (53° 6.2' latitude, 7° 12.6' longitude) with seventeen Enercon E-66 1.8 MW turbines of 98 m hub height and with 3-blade propellers of 35 m blade length. The turbines have a variable speed increasing with wind velocity, starting with 10 rpm (revolutions per minute) at a wind velocity of 2.5 m/s at hub height up to 22 rpm at wind velocities of 12 m/s and over.

At the Dutch side of the border is a residential area along the Oude Laan and Veendijk in De Lethé (see figure IV.2): countryside dwellings surrounded by trees and agricultural fields. The dwelling nearest to the wind farm is some 500 m west of the nearest wind turbine (nr. 16). According to a German noise assessment study a maximum immission level of 43 dB(A) was expected, 2 dB below the relevant German noise limit. According to a Dutch consultancy immission levels would comply with Dutch (wind velocity dependent) noise limits.

After the farm was put into operation residents made complaints about the noise, especially at (late) evening and night. The residents, united in a neighbourhood group, could not persuade the German operator into mitigation measures or an investigation of the noise problem and brought the case to court. The Science Shop for Physics had just released a report explaining a possible discrepancy between calculated and real sound immission levels of wind turbines because of changes in wind profile, and was asked to investigate the consequences of this discrepancy by sound measurements. Although at first the operator agreed to supply measurement data from the wind turbines (such as power output, rotation speed, axle direction), this was withdrawn after the measurements had started. All relevant data therefore had to be supplied or deduced from our own measurements.

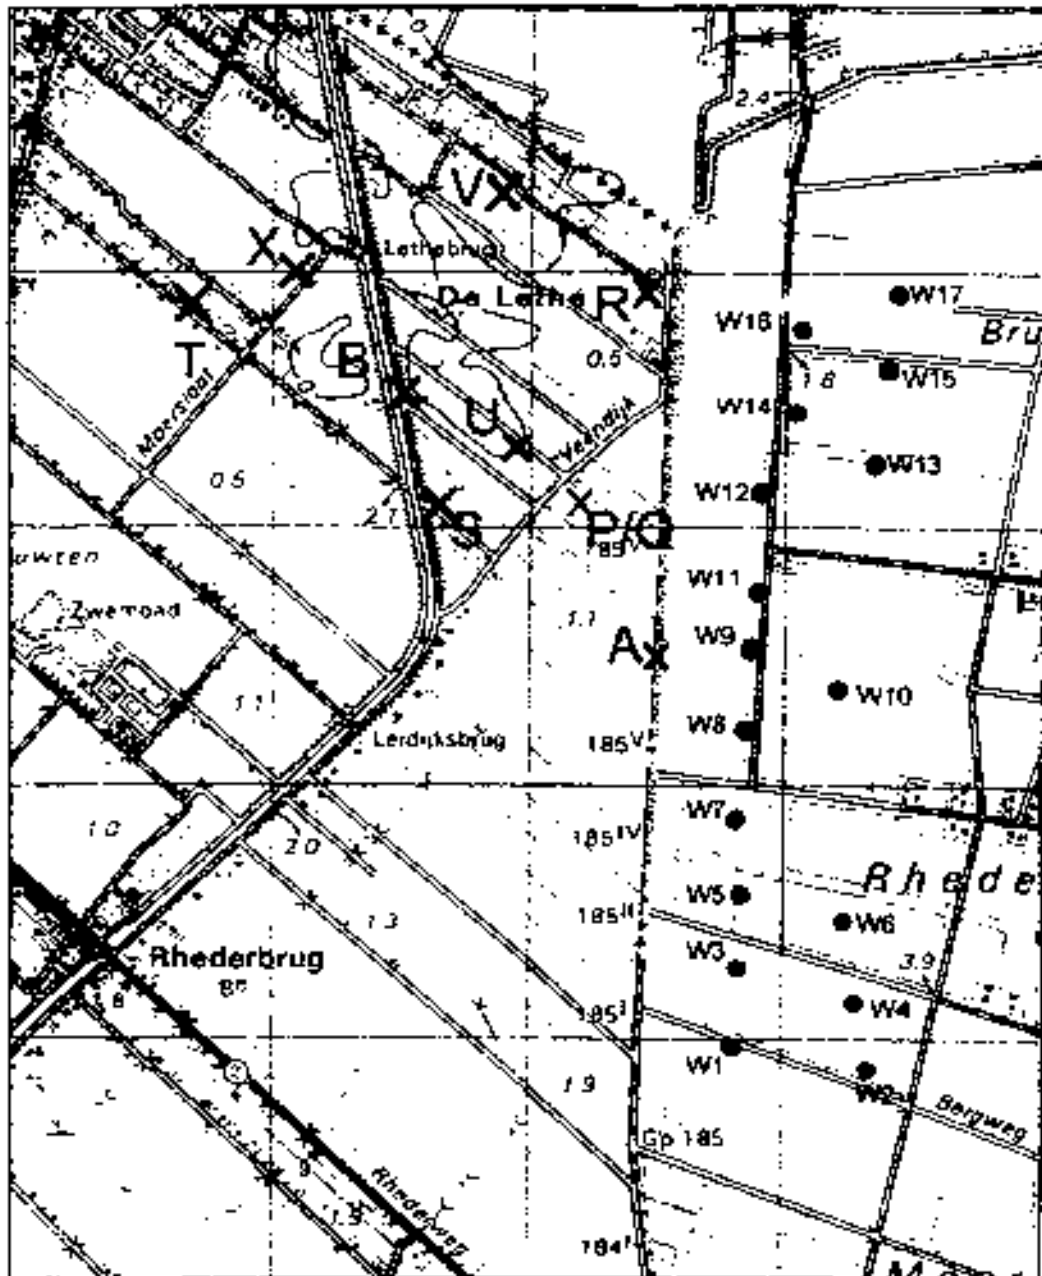

Figure IV.2: turbines (dots W1 – W17) in and measurement locations (crosses A...X) near the Rhede wind farm; Dutch – German border indicated by line of + + + (through A); grid lines are 1 km apart, north is at top

Figure IV.1: the Rhede wind farm, view from the north-northwest

IV.2 Noise impact assessment

In the Netherlands and Germany noise impact on dwellings near a wind turbine or wind farm is calculated with a sound propagation model. Wind turbine sound power levels L_w are used as input for the model, based on measured or estimated data. In Germany a single 'maximum' sound power level (at 95% of maximum electric power) is used to assess sound impact. In the Netherlands sound power levels related to wind velocities at 10 m height are used; the resulting sound immission levels are compared to wind velocity dependent noise limits (see figure VII.1). Implicitly this assessment is based on measurements in daytime and does not take into account atmospheric conditions affecting the wind profile, especially at night.

In the Netherlands a national calculation model is used [VROM 1999] to assess noise impact, as is the case in Germany [TA-Lärm 1998]. According to Kerkers [Kerkers 1999] there are, at least in the case of these wind turbines, no significant differences between both models.

In both sound propagation models the sound immission level L_{imm} at a specific observation point is a summation over j sound power octave band levels L_w , of k sources (turbines), reduced with attenuation factors $D_{j,k}$:

$$L_{imm} = 10 \cdot \log \left\{ \sum_j \sum_k 10^{0.1 \cdot (L_w - D_{j,k})} \right\} \quad (IV.1)$$

L_{w_j} , assumed identical for all k turbines, is a function of rotational speed. D_j is the attenuation due to geometrical spreading (D_{geo}), air absorption (D_{j-air}) and ground absorption ($D_{j-ground}$): $D_{j,k} = D_{geo,k} + D_{j-air,k} + D_{j-ground,k}$. Formula (IV.1) is valid for a downwind situation. For long term assessment purposes a meteorological correction factor is applied to (IV.1) to account for 'average atmospheric conditions'. When comparing calculated and measured sound immission levels in this study no such meteo-correction is applied because measurements were always downwind of a turbine or the wind farm.

IV.3 Wind turbine noise perception

There is a distinct audible difference between the night and daytime wind turbine sound at some distance from the turbines. On a summer's day in a moderate or even strong wind the turbines may only be heard within a few hundred meters and one might wonder why residents should complain of the sound produced by the wind farm. However, in quiet nights the wind farm can be heard at distances of up to several kilometers when the turbines rotate at high speed. In these nights, certainly at distances from 500 to 1000 m from the wind farm, one can hear a low pitched thumping sound with a repetition rate of about once a second (coinciding with the frequency of blades passing a turbine mast), not unlike distant pile driving, superimposed on a constant broad band 'noisy' sound. A resident living at 1 km from the nearest turbine says it is the rhythmic character of the sound that attracts attention: beats are clearly audible for some time, then fade away to come back again a little later. A resident living at 2.3 km from the wind farm describes the sound as 'an endless train'. In daytime these pulses are usually not audible and the sound from the wind farm is less intrusive or even inaudible (especially in strong winds because of the then high ambient sound level).

In the wind farm the turbines are audible for most of the (day and night) time, but the thumping is not evident, although a 'swishing' sound – a regular variation in sound level – is readily discernible. Sometimes a rumbling sound can be heard, but it is difficult to assign it, by ear, to a specific turbine or to assess its direction.

IV.5 Measurement instruments and method

Sound immission measurements were made over 1435 hours, of which 417 hours at night, within four months on two consecutive locations with an unmanned Sound and Weather Measurement System (SWMS) consisting of a sound level meter (type 1 accuracy) with a microphone at 4.5 m height fitted with a 9 cm diameter foam wind shield, and a wind meter at 10 m as well as at 2 m height. Every second wind velocity and wind direction (at 10 m and at 2 m height) and the A-weighted sound level were measured; the measured data were stored as statistical distributions over 5 minute intervals. From these distributions all necessary wind data and sound levels can be calculated, such as average wind velocity, median wind direction or equivalent sound level and any percentile (steps of 5%) wind velocity, wind direction or sound level, in intervals of 5 minutes or multiples thereof.

Also complementary measurements were done with logging sound level meters (type 1 and 2 accuracy) and a spectrum analyser (type 1) to measure immission sound levels in the residential area over limited periods, and emission levels near wind turbines. Emission levels were measured according to international standards [IEC 1998, Ljunggren 1997], but for practical purposes they could not be adhered to in detail: with respect to the recommended values a smaller reflecting board was used for the microphone (30·44 cm² instead of a 1 m diameter circular board) and a smaller distance to the turbine (equal to tower height instead of tower height + blade length); reasons for this were given in Chapter II. Also it was not possible to do emission measurements with only one turbine in operation.

IV.6 Results: sound emission

Emission levels L_{eq} measured very close to the centre of a horizontal, flat board at a distance R from a turbine hub can be converted to a turbine sound power level L_w [IEC 1998, Ljunggren 1997]:

$$L_w = L_{eq} - 6 + 10 \cdot \log(4\pi \cdot R^2 / A_0) \quad (IV.2)$$

where A_0 is a unit surface (1 m²). From earlier measurements [Kerkers 1999] a wind velocity dependence of L_w was established as given in table

IV.1. As explained above, the wind velocity at 10 m height was not considered a reliable single measure for the turbine sound power, but rotational speed was a better measure.

Emission levels have been measured, typically for 5 minutes per measurement, at nine turbines on seven different days with different wind conditions. The results are

plotted in figure IV.3; the sound power level is plotted as a function of rotational speed N . N is proportional to wind velocity at hub height and could be determined by counting, typically during one minute, blades passing the turbine mast. This counting procedure is not very accurate (accuracy per measurement is ≤ 2 counts, corresponding to 2/3 rpm) and is probably the dominant reason for the spread in figure IV.3. The

Figure IV.3: measured wind turbine sound power level L_w as a function of turbine rotational speed N

best logarithmic least squares fit to the data points in figure IV.3 is:

$$L_w = 67.1 \cdot \log(N) + 15.4 \text{ dB(A)} \tag{IV.3}$$

with a correlation coefficient of 0.98. The standard deviation of measurement values with respect to this fit is 1.0 dB.

Table IV.1: sound power level of wind turbines [Kerkers 1999]

wind velocity V_{10}	m/s	5	6	7	8	9	10
sound power level L_w	dB(A)	94	96	98	101	102	103

Table IV.2: octave band spectra of wind turbines at $L_w = 103$ dB(A)

frequency	Hz	63	125	250	500	1000	2000	4000	L_w
this report	dB(A)	82	92	94	98	98	93	88	103
[Kerkers 1999]	dB(A)	85	91	95	98	98	92	83	103

At the specification extremes of 10 rpm and 22 rpm the (individual) wind turbine sound power level L_w is 82.8 dB(A) and 105.7 dB(A), respectively. In table IV.2 earlier measurement results [Kerkers 1999] are given for the octave band sound power spectrum. Also in table IV.2 the results of this study are given: the logarithmic average of four different spectra at different rotational speeds. In all cases spectra are scaled, with formula IV.3, to the same sound power level of 103 dB(A).

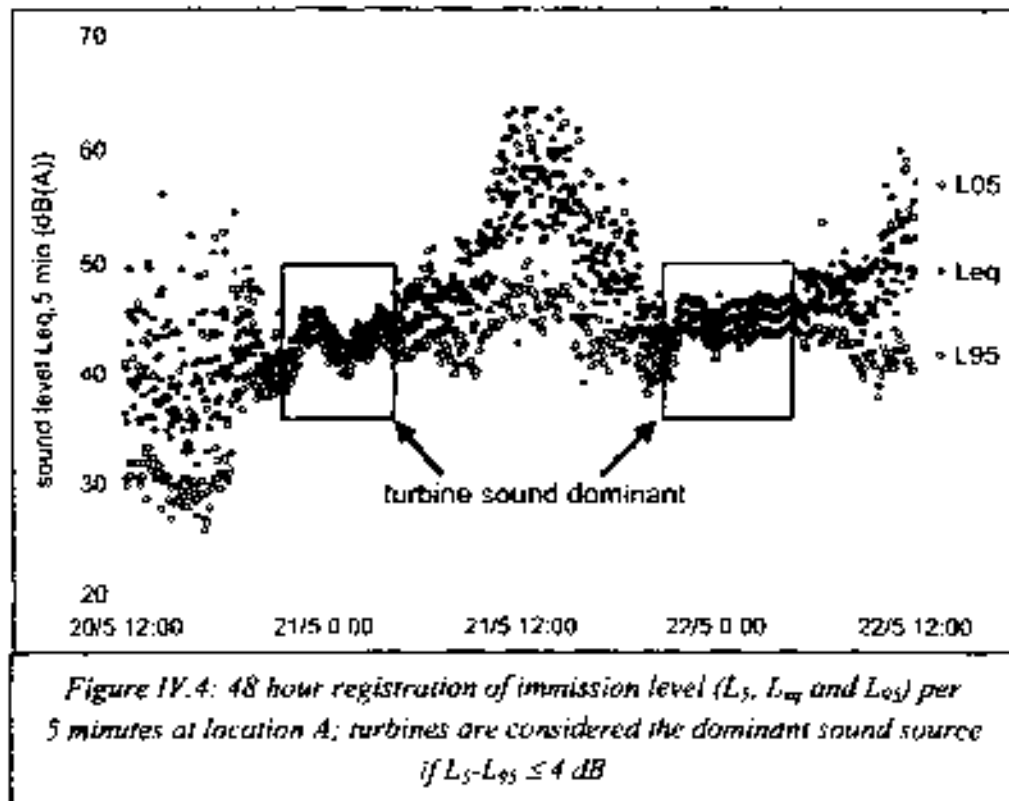

To calculate sound immission levels at a specific rotational speed (or vice versa) the sound power level given in formula (IV.3), and the spectral form in table IV.2 ('this report') have been used.

IV.7 Results: sound immission

The sound immission level has been measured with the unmanned SWMS on two locations. From May 13 until June 22, 2002 it was placed amidst open fields with barren earth and later low vegetation at 400 meters west of the westernmost row of wind turbines (location A, see figure IV.2). This site was a few meters west of the Dutch-German border, visible as a ditch and a 1.5 to 2 m high dike. From June 22 until September 13, 2002 the SWMS was placed on a lawn near a dwelling at 1500 m west of the westernmost row (location B), with low as well as tall trees in the vicinity. On both locations there were no reflections of turbine sound towards the microphone, except via the ground, and no objects (such as trees) in the line of sight between the turbines and the microphone. Apart from possible wind induced sound in vegetation relevant sound sources are traffic on rather quiet roads, agricultural activities, and birds. As, because of the trees, the correct (potential) wind velocity and direction could not be measured on location B, wind measurement data provided by the KNMI were used from their Nieuw Beerta site 10 km to the north. These data fitted well with the measurements on location A.

At times when the wind turbine sound is dominant, the sound level is relatively constant within 5 minute intervals. In figure IV.4 this is demonstrated for two nights. Thus measurement intervals with dominant turbine sound could be selected with a criterion based on a low variation in sound level: $L_5 - L_{95} \leq 4$ dB, where L_5 and L_{95} are the 5 and 95 percentile

sound level in the measurement interval. In a normal (Gaussian) distribution this would equal $\sigma \leq 1.2$ dB, with σ the standard deviation.

On location A, 400 m from the nearest turbine, the total measurement time was 371 hours. In 25% of this time the wind turbine sound was dominant, predominantly at night (23:00 - 6:00 hours: 72% of all 105 nightly hours) and hardly in daytime (6:00 - 19:00 hours: 4% of 191 hours). See table IV.3.

On location B, 1500 m from the nearest turbine, these percentages are almost halved, but still the turbine sound is dominant for over one third of the time at night (38% of 312 hours). The trend in percentages agree with complaints concerning mostly noise in the (late) evening and at night and their being more strongly expressed by residents closer to the wind farm.

Table IV.3: total measurement time in hours and selected time with dominant wind turbine sound

Location	total time (hours and % of total measurement time at location)	Night 23:00-6:00	Evening 19:00-23:00	Day 6:00-19:00
A: total	371 h	105	75	191
A: selected	92 h 25%	76 72%	9 12%	7 4%
B: total	1064 h	312	183	569
B: selected	136 h 13%	119 38%	13 7%	4 0,7%

In figure IV.5 the selected ($L_5 - L_{95} \leq 4$ dB) 5 minute equivalent immission sound levels $L_{eq,5min}$ are plotted as a function of wind direction (left) and of wind velocity (right) at 10 m height, for both location A (above) and B (below). The KNMI wind velocity data (used for location B) were given as integer values of the wind velocity.

Also the wind velocity at 10 m and 2 m height on location A are plotted (in IV.5A and IV.5B, respectively), and the local wind velocity (influenced by trees) at 10 m on location B (IV.5C). The immission level data points are separated in two classes where the atmosphere was stable or neutral, according to observations of wind velocity and cloud cover at Eelde. Eelde is the nearest KNMI site for these observations, but it is 40 km to the west, so not all observations will be valid for our area.

In figure IV.5B a grey line is plotted connecting calculated sound levels with sound power levels according to table IV.1 (the lowest value at 2.5 m/s is extrapolated [Van den Berg *et al* 2002]), implicitly assuming a fixed logarithmic wind profile according to formula (III.2). If this line is compressed in the direction of the abscissa with a factor 2.6, the result is a (black) line coinciding with the maximum one hour values ($L_{eq,1h}$). Apparently for data points on this line the sound emission corresponds to a wind velocity at hub height that is 2.6 times higher than expected. In figure IV.6 this is given for one hour periods: all 5 minute measurement periods

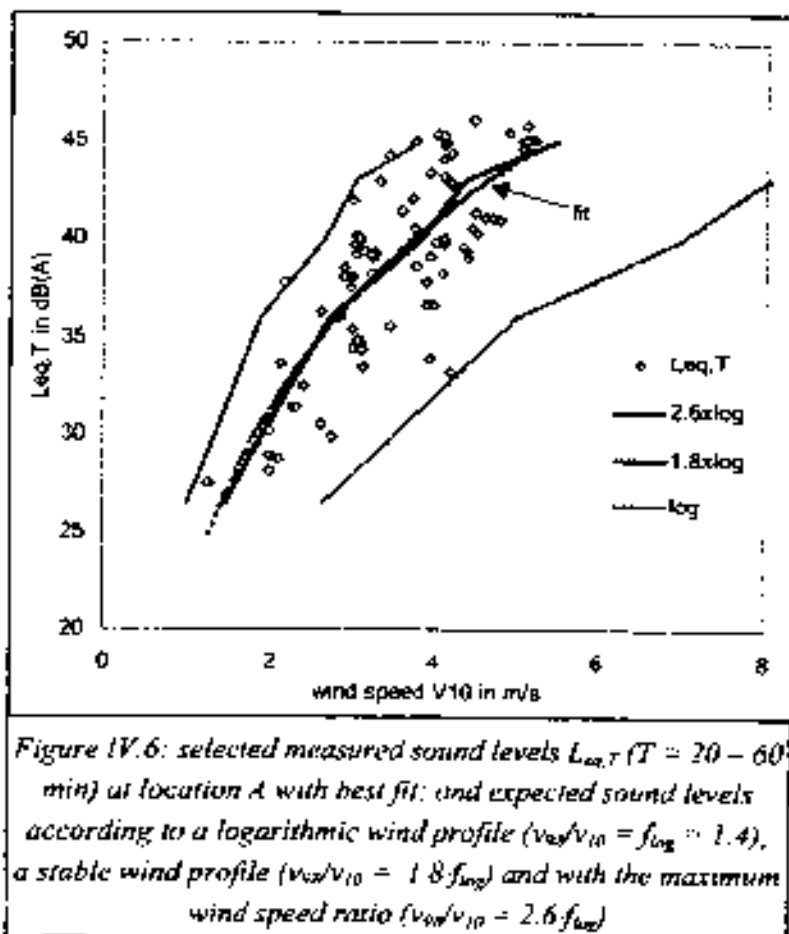

Figure IV. 5: measured sound levels $L_{max,5,min}$ at locations A (above) and B (below) as a function of median wind direction (left) and average wind speed (right) at reference height (10 m), separated in classes where the atmosphere at Eelde was observed as stable (open diamonds) or neutral (black dots). Also plotted are expected sound levels according to logarithmic wind profile and wind speed at reference height (grey lines in B and D), and at a 2.6 times higher wind speed (black lines in B and D). Figures A, B and C also contain the wind speed v_{10} (A), v_7 (B), and the local v_{10} (C) disturbed by trees, respectively.

that satisfied the L_5 - L_{95} -criterion, with at least 4 periods per hour, were taken together in consecutive hourly periods and the resulting $L_{eq,T}$ ($T = 20$ to 60 minutes) was calculated. The resulting 83 $L_{eq,T}$ -values are plotted against the average wind velocity V_{10} . Also plotted in figure IV.6 are the expected immission levels assuming a logarithmic wind profile calculated from (III.4), with $f_{log} = (V_{90}/V_{10})_{log} = 1.4$ (for f_{cs} ; see text above equation (II.4); the immission levels assuming a stable wind profile with $m = 0.41$, so $f_{stable} = 2.5 = 1.8 \cdot f_{log}$; the maximum immission levels assuming $f_{max} = 3.7$

$= 2.6 \cdot f_{log}$, in agreement with a wind profile (III.2) with $m = 0.57$. The best fit of all data points ($L_{eq,T}$) in figure IV.6 is $L_{eq} = 32 \cdot \log(V_{10}) + 22$ dB (correlation coefficient 0.80) with $1 < V_{10} < 5.5$ m/s. This agrees within 0.5 dB with the expected level according to the stable wind profile. The best fit of all 5 minute data-points in figure IV.5B yields the same result.

Thus on location A the highest one hour averaged hub height wind velocities at night are 2.6 times the expected values according to the logarithmic wind profile in formula (III.4). As a consequence, sound levels at (in night-time) frequently occurring wind velocities of 3 and 4 m/s are 15 dB higher than expected, 15 dB being the vertical distance between the expected and highest one-hour immission levels at 3- 4 m/s (upper and lower lines in figures 5B and 6).

The same lines as in figure IV.5B, but valid for location B, are plotted in figure IV.5D; immission levels here exceed the calculated levels, even if calculated on the basis of a 2.6 higher wind velocity at hub height. An explanation may be that a lower ambient sound level is necessary compared to location A to allow wind turbine sound to be dominant at location B (as selected with the $L_5 - L_{95}$ -criterion), implying a lower near ground wind velocity and thus a higher stability. It may also be caused by an underestimate of actual sound level in the calculation model for long distances, at least for night conditions (this issue will be addressed in section IV.10).

As is clear from the wind velocity at 2 m height plotted in figure IV.5B, there is only a very light wind near the ground even when the turbines rotate at high power. This implies that in a quiet area with low vegetation the ambient sound level may be very low. The contrast between the turbine sound and the ambient sound is therefore at night higher than in daytime.

Although at most times the wind turbine sound dominates the sound levels in figure IV.5, it is possible that at low sound levels, *i.e.* at low rotational speeds and low wind velocities, the $L_5 - L_{95}$ -criterion is met while the sound level is not entirely determined by the wind turbines. This is certainly the case at levels close to 20 dB(A), the sound level meter noise floor. The long term night-time ambient background level, expressed as the 95-percentile (L_{95}) of all measured night-time sound levels on location B, was 23 dB(A) at 3 m/s (V_{10}) and increasing with $3.3 \text{ dB/m}\cdot\text{s}^{-1}$ up to $V_{10} = 8 \text{ m/s}$ [Van den Berg *et al* 2002]. Comparing this predominantly non-turbine background level with the sound levels in figure IV.5B and 5D, it is clear that the lowest sound levels may not be determined by the wind turbines, but by other ambient sounds (and instrument noise). This wind velocity dependent, non-turbine background sound level L_{95} is, however, insignificant with respect to the highest measured levels. Thus, the high sound levels do not include a significant amount of ambient sound not coming from the wind turbines. This has also been verified in a number of evenings and nights by personal observation.

IV.8 Comparison of emission and immission

sound levels

From the 30 measurements of the equivalent sound level $L_{\text{eq},T}$ (with T typically 5 minutes) measured at distance R from the turbine hub (R typically $100\sqrt{2}$ m), a relation between sound power level L_w and rotational speed N of a turbine could be determined: see formula (IV.3).

This relation can be compared with the measured immission sound level $L_{\text{imm},T}$ ($T = 5$ minutes) at location A, 400 m from the wind farm (closest turbine), in 22 cases where the rotational speed was known. The best logarithmic fit for the data points of the immission sound level L_{imm} as a function of rotational speed N is:

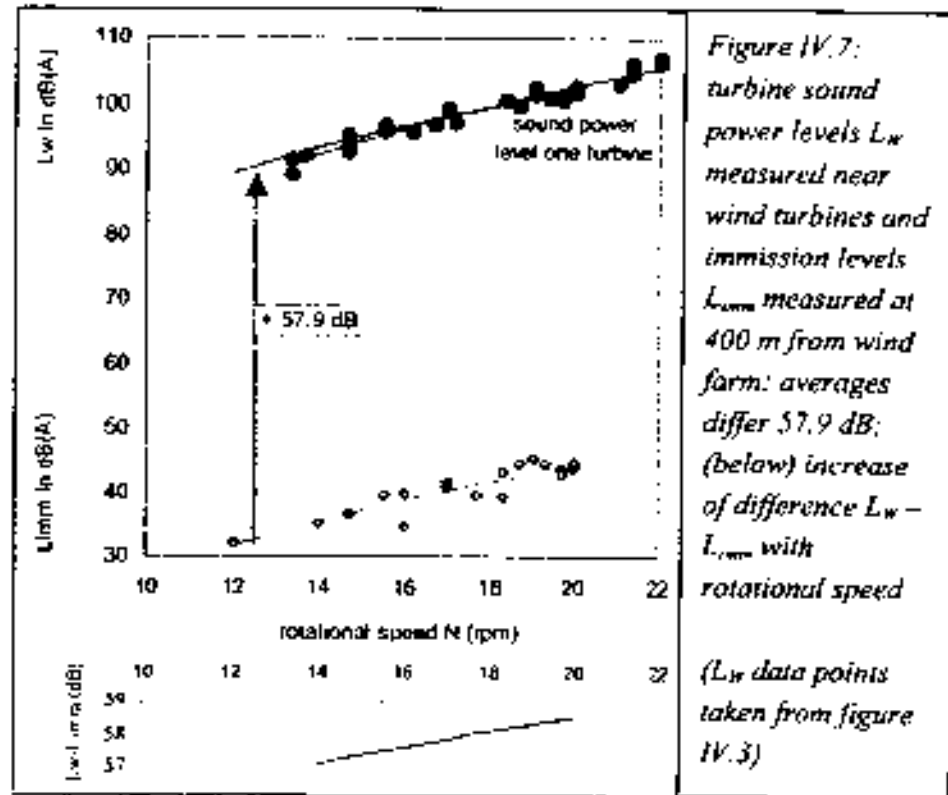

$$L_{\text{imm}} = 57.6 \cdot \log(N) - 30.6 \text{ dB(A)} \quad (\text{IV.4})$$

with a correlation coefficient of 0.92 and a standard deviation of 1.5 dB with respect to the fit. Both relations from formulae (IV.3) and (IV.4) and the datapoints are given in figure IV.7. The difference between both relations is $L_w - L_{\text{imm}} = 9.5 \cdot \log(N) + 46.0$ dB. For the range 14 – 20 rpm, where both series have data points, the average difference is 57.9 dB, the maximum deviation from this average is 0.8 dB (14 rpm: 57.1 dB(A); 20 rpm: 58.6 dB(A); see lower part of figure IV.7). It can be shown by calculation that about half of this deviation can be explained by the variation of sound power spectrum with increasing speed N .

The sound immission level can be calculated with formula (IV.1). For location A, assuming all turbines have the same sound power L_w , this leads to $L_w - L_{\text{imm}} = 58.0$ dB. This is independent of sound power level or rotational speed, as it is calculated with a constant spectrum averaged over several turbine conditions, *i.e.* turbine speeds. The measured difference (57.9 dB) matches very closely the calculated difference (58.0 dB).

The variation in sound immission level at a specific wind velocity V_{10} in figures IV.5B and IV.5D is thus seen to correspond to a variation in rotational speed N , which in turn is related to a variation in wind velocity

at hub height, not to a variation in V_{10} . At location A, N can be calculated from the measured immission level with the help of formula (IV.4) or its inverse form: $N = 3,4 \cdot 10^{(L_{imm}/37,6)}$.

IV.9 Atmospheric stability and Pasquill class

In figure IV.5 measurement data have been separated in two sets according to atmospheric stability in Pasquill classes, supplied by KNMI from their measurement site Eelde, 40 km to the west of our measurement site. Although the degree of stability will not always be the same for Eelde and our measurement location, the locations will correlate to a high degree in view of the relatively small distance between them. For night-time conditions 'stable' refers to Pasquill classes E and F (lightly to very stable) and corresponds to $V_{10} \leq 5$ m/s and cloud coverage $C \leq 50\%$ or $V_{10} \leq 3.5$ m/s and $C \leq 75\%$, 'neutral' (class D) corresponding to all other situations. Although from figure IV.5 it is clear that the very highest sound levels at an easterly wind ($\approx 80^\circ$) do indeed occur in stable conditions, it is also

clear that in neutral conditions too the sound level is higher than expected for most of the time, the expected values corresponding to the grey lines in figures IV.5B and D, derived from daytime conditions. According to this study the sound production, and thus wind velocity at 100 m height is at night often higher than expected, in a stable, but also in a neutral atmosphere. On the other hand, even in stable conditions sound levels may be lower than expected (i.e. below the grey lines), although this occurs rarely. It may be concluded from these measurements that a logarithmic wind profile based only on surface roughness does not apply to the night-time atmosphere in our measurements, not in a stable atmosphere and not always in a neutral atmosphere when determined from Pasquill classes.

IV.10 Additional measurements

In several nights in the period that the SMWS was measuring at location A, manual measurements were performed at a number of locations in the area between 0.6 and 2.3 km west of the wind farm. The locations are plotted in figure IV.2. Most locations were close to dwellings, but two (locations U and X) were in open fields. Locations P and Q are close and at the same distance from the western row of turbines and can be considered equal with respect to the turbines (Q was chosen instead of P as P was at the verge of a garden with a loud bird chorus in the early morning). The surface of most of the area is covered with grass and low crops, with trees at some places. For these measurements one or more logging sound level meters (accuracy type 1 or 2) were used simultaneously, storing a broad band A-weighted sound pressure level every second. Before and after measurement the meters were calibrated with a 94.0 dB, 1000 Hz calibration source, and as a result measurement accuracy due to the instruments is within 0.2 dB. On every location the microphone was in a 10 cm spherical foam wind screen approximately 1.2 m above the surface. There were no reflections of the wind turbine sound to the microphone, except via the ground.

IV.10.1 Measured and calculated immission sound levels

Figure IV.8 gives a simultaneous registration from just before midnight on May 17, 2002, till noon on May 18, of the equivalent sound pressure levels per 5 minutes at locations A (from the SWMS), P/Q and U (from the manual meters) at distances to the westernmost row of turbines of 400, 750 and 1050 m, respectively. In the night hours the sound of the turbines was dominant at each of these locations, apart from an occasional bird or car. Also plotted in figure IV.8 are the wind velocity at 2 and 10 m heights at location A.

A short decrease in wind velocity at around 2:00 is apparently accompanied by a similar decrease in wind velocity at hub height, as the sound level varies much in the same way. However, the registrations show that the sound level increases from 0:30 until 6:00 while the 10-m wind velocity does not show a net increase in this period. In fact the sound level at location A at 3:00 implies a rotational speed of 21 rpm, which is just below maximum (22 rpm), even though the wind velocity at 10 m height is

only 4.5 m/s and at 2 m height is less than 1 m/s. Only occasionally there are other sounds until the dawn chorus of birds just after 4:00 and after that the near-ground wind picks up.

In figure IV.9 the 5-minute equivalent sound levels at P/Q and U relative to the sound level at A are plotted. The advantage of taking the sound level at A as a reference value is that it is not necessary to know the exact sound power level of the turbines themselves. The level differences are 3.5 and 6.5 dB, respectively, with a variation of ± 1 dB. The variations must be due to differences in sound propagation mostly, because other disturbances (such as one at 23:55 at P) are rare.

Figure IV.9: difference between simultaneously measured broad band A-weighted immission levels at locations U and P/Q and at location A

Comparable simultaneous measurements have been made in the night of June 2 - 3 and of June 17 - 18, 2002. In Appendix C the registrations are given, as well as the level differences between the distant locations P through T, V and X and the reference location A. The measured and calculated decrease in sound level with distance, relative to location A, as well as the discrepancy between both, are given in table IV.4 and figure IV.10. In all cases the wind was easterly ($60^\circ - 100^\circ$), that is: from the

wind farm to the measurement location. Also there was little near-ground wind and low background sound levels from other sources.

The calculated differences have been determined with equation IV.1 and the Dutch national model [VROM 1999]. The measured differences in table IV.4 are the difference in the equivalent sound level at a location minus the same at location A over the given measurement time T; only very few of the $L_{eq,5min}$ values were omitted from this $L_{eq,T}$ because they were apparently disturbed by another sound. To minimize influence of possible disturbing sounds the median of all $L_{eq,5min}$ values can be used, as this value gives the prevailing difference and is thus less sensitive to the influence of disturbances; this, however, yields the same results within 0.5 dB.

The discrepancies between measured and calculated levels are small, especially considering the large distances involved: -0.2 to 1.5 dB. One may conclude that the calculation model is quite satisfactory in this relatively simple situation (a high sound source above flat ground).

Table IV.4: measured and calculated differences in sound level $L_{eq,T}$ at locations R - T and at location A, when wind blows from the wind farm

location	R	P/Q	U	V	S	X	T
distance to western row wind farm (m)	600	750	1000	1100	1250	1900	2250
date of measurement (in 2002)	June 2/3	May 17/18, June 2/3 -18	May 17/18	June 18	June 2/3	June 18	June 2/3
measurement time T (min.)	200	295+200+115	120	140	190	85	195
measured difference	-3.5	-3.8 *	-6.4	-9.1	-8.5	12.1	-1.3
calculated difference	-4.5	-4.1	-6.6	-10.6	-8.3	-13.1	-14.2
discrepancy calculation - measurement	-1.0	-0.3	-0.2	-1.5	0.2	-1.0	-12.9

*: measurement time weighted logarithmic average of resp. 3.5, 3.6 and 4.6 dB

In figure IV.10 a line is plotted corresponding to $-20 \cdot \log(R/R_0)$, where R_0 is the distance from A to the western turbine row. This decrease corresponds to spherical divergence from a point source only, with no attenuation due to absorption. It is clear that, with the exception of location T (see next section), the measured decrease is close to this spherical divergence: the measured values at the locations P/Q, U, S and X are 1.4 to 1.7 dB above the plotted line, at the more northern locations R and V they are 0 to 0.3 dB below the line. Approximately the same is true for the calculated levels: the calculated values at the locations P/Q, U, S and X are 0.4 to 1.6 dB above the plotted line, at the more northern locations R and V they are 1.0 to 1.8 dB below the line.

Figure IV.10: measured and calculated decrease in immission sound level due to the wind farm at locations P through X relative to location A, and the discrepancy between both; the straight line corresponds to $-20 \cdot \log(R/R_0)$

There are two counteracting causes explaining this apparently 'almost spherical' attenuation. The first is that the wind farm cannot be considered a point source. Due to its large dimension (3 km from south to north, see figure IV.2) normal to the shortest distance from location A and locations further west, the geometrical divergence should be between cylindrical and

spherical divergence, that is: proportional to $-X \cdot \log(R/R_A)$, with $10 < X < 20$. Secondly one expects a decrease due to absorption ('excess attenuation') above the decrease due to geometrical divergence: for the Rhede turbines calculation shows that this excess attenuation is expected to be 1.7 dB per km.

IV.10.2 Immission level increase due to inversion layer?

In the night of June 2 to 3, 2002, high sound levels were measured at the most distant measurement location T, 2250 m from the wind farm. The immission sound level varied between approximately 40 and 45 dB(A) and was more variable than at the other locations (see Appendix C). The resident close to this measurement location could hear the wind farm well, at 22:30 hours describing it as: "The sound changes from 'an endless train' to a more pulsating sound; the sound grows louder en sharper. At the background is a kind of humming, comparable to the sound of a welding transformer". The sound was audible indoors.

In our research we have not met this phenomenon again. However, mr. Flight living near another wind farm south of the Rhede wind farm observed the same phenomenon: on a location appr. 750 m from the closest turbine, where at night he usually measured an immission level of 42 to 44 dB(A), he measured a level of 50 to 52 dB(A) in the night of September 24, 2002. It was clear that the sound came from the nearest wind farm, but also from a second, more distant wind farm that usually was not audible here. Again, the atmosphere was stable and there was a weak near-ground easterly wind, blowing from the wind farm to the observer.

This may be a result of strong refraction of sound below an inversion layer. This inversion layer must be at or above the rotor to have the highest effect, so at or above 130 m (= hub height + blade length).

Suppose the turbines in the Rhede wind farm each have a sound power level L_w at a certain wind velocity. If we substitute the entire farm by one single turbine at the site of the turbine closest to location T (nr. 12), it can be calculated that the sound level of that single turbine must be $L_w + 9.4$ to produce the same immission level at T as the entire wind farm.

Considering only spherical spreading, this immission level is $L_{imm} = L_w + 9.4 - 10 \cdot \log(4\pi \cdot 2250^2) = L_w - 68.6$. Now the sound waves will be refracted downwards at the inversion layer and we assume that all sound propagates below the inversion layer. At large distances (\gg height inversion layer) this is equivalent to sound spreading cylindrically from a vertical line source. To simulate this we replace the substitute single turbine, which was modelled as a point source at hub height, by a vertical line source from the ground up to the inversion layer height (130 m). If the sound power levels of both point and line source are equal, the line source must have a sound power level of $L_w' = L_w + 9.4 - 10 \cdot \log(130) = L_w - 11.7$ dB/m. If again the sound level decreases by geometrical (now: cylindrical) spreading only, the sound immission level at 2250 m from this line source is $L_{imm}' = L_w - 11.7 - 10 \cdot \log(2\pi \cdot 2250) = L_w - 54.6$ dB. Comparison of the immission level due to a point source ($L_w - 68.6$) and a line source ($L_w - 54.6$) shows that the line source causes a 14 dB higher immission level. This simple calculation shows that the rise in level caused by a simplified high inversion layer is close to the observed increase (13 dB): the higher level is a result of the sound being 'trapped' below the inversion layer. However, more observations and data are needed to verify this hypothesis.

IV.11 Conclusion

Sound immission measurements have been made at 400 m (location A) and 1500 m (location B) from the wind farm Rhede with 17 tall (98 m hub height), variable speed wind turbines. It is customary in wind turbine noise assessment to calculate immission sound levels assuming wind velocities based on wind velocities V_{10} at reference height (10 m) and a logarithmic wind profile. Our study shows that the immission sound level may, at the same wind velocity V_{10} at 10 m height, be significantly higher in night-time than in daytime. A 'stable' wind profile predicts a wind velocity V_h at hub height 1.8 times higher than expected and agrees excellently with the average measured night-time sound immission levels. Wind velocity at hub height may still be higher: at low wind velocities V_{10} up to 4 m/s, the wind velocity v_h is at night up to 2.6 times higher than expected.

Thus, the logarithmic wind profile, depending only on surface roughness and not on atmospheric stability, is not a good predictor for wind profiles at night. Especially for tall wind turbines, estimates of the wind regime at hub height based on the wind velocity distribution at 10 m, will lead to an underestimate of the immission sound level at night: at low wind velocities ($V_{10} < 5$ m/s) the actual sound level will be higher than expected for a significant proportion of time. This is not only the case for a stable atmosphere, but also -to a lesser degree- for a neutral atmosphere.

The change in wind profile at night also results in lower ambient background levels than expected: at night the wind velocity near the ground may be lower than expected from the velocity at 10 m and a logarithmic wind profile, resulting in low levels of wind induced sound from vegetation. The contrast between wind turbine and ambient sound levels is therefore at night more pronounced.

Measured immission sound levels at 400 m from the nearest wind turbine almost perfectly match (average difference: 0,1 dB) sound levels calculated from measured emission levels near the turbines. From this it may be concluded that both the emission and immission sound levels could be determined accurately, even though the emission measurements were not fully in agreement with the standard method. As both levels can be related through a propagation model, it may not be necessary to measure both: the immission measurements can be used to assess immission as well as emission sound levels.

At greater distances the calculated level may underestimate the measured level, but considering the distances involved (up to 2 km) the discrepancy is small: 1,5 dB or less.

In one night the sound level at a distant location (over 2 km from the wind farm) was much higher than expected, perhaps because of an inversion layer adding more downward refracted sound. It apparently is a rare occurrence at the Rhede wind farm, and could be more significant where high inversion layers occur more often.

V THE BEAT IS GETTING STRONGER: low frequency modulated wind turbine sound

V.1 *Effects of atmospheric stability*

Atmospheric stability is not only relevant for wind turbine sound *levels*, as we saw in the preceding chapter, but also for the *character* of the sound. In conditions where the atmosphere is stable, distant wind turbines can produce a beating or thumping sound that is not apparent in daytime.

The magnitude of the effects of increasing stability depends on wind turbine properties such as speed, diameter and height. We will use the dimensions of the wind turbines in the Rhede wind farm, that are typical for a modern variable speed 2 MW wind turbine: hub height 100 m, blade length 35 m and blade tip speed increasing with wind velocity up to a maximum value of $\Omega \cdot R = 81$ m/s (at 22 rpm). Here a speed of 20 rpm (70 m/s) will be used as this was typical for situations where at the Rhede wind farm a clear beating sound was heard.

We will assume the optimum angle of attack α is 4° . The change in trailing edge (TE) sound pressure level SPL_{TE} with the angle of attack from this optimum up to 10° can be approximated by $\Delta SPL_{TE}(\alpha) = 1.5 \cdot \alpha - 1.2$ dB or $d(\Delta SPL_{TE})/d\alpha = 1.5$ (see appendix B, equation B.8). When the pitch angle is constant, the change in angle of attack due to a variation dV in wind velocity is $d\alpha = 0.84 \cdot dV$ (see appendix B, equation B.9).

To calculate vertical wind velocity gradients the simple engineering formula (III.1) will be used: $V_h = V_{ref}(h/h_{ref})^m$ (see section III.2). In the text below we will use a value $m = 0.15$ for a daytime atmosphere (unstable - neutral), $m = 0.4$ for a stable, and $m = 0.65$ for a very stable atmosphere (see table III.1).¹ These values will be used for altitudes between 10 and 120 m.

¹ A value $m = 0.65$ is not obvious from table III.1, but is chosen as a relatively high value that is exceeded for a small part of the time (see figures VI.6 and VI.16, and section VI.6)

There are now three factors influencing blade swish level when the atmosphere becomes more stable: a) the higher wind velocity gradient, b) the higher wind direction gradient, and c) the relative absence of large scale turbulence.

a. Wind velocity gradient. Rotational speed is determined by a rotor averaged wind velocity, which here is assumed to be the induced wind velocity at hub height (equation III.5). The free, unobstructed wind at height h is denoted by V_h , the induced wind speed at the blade by $V_{h,b}$. With increasing atmospheric stability the difference in wind velocity between the upper and lower part of the rotor increases. As in a complete rotation the pitch angle is constant the change in angle of attack due to a change in induced wind velocity is $d\alpha = 0.82 \cdot dV_{h,b}$ which can be expressed in a change of the free wind velocity by $d\alpha = 0.82 \cdot (2/3) \cdot dV_h = 0.55 \cdot dV_h$ (see equation III.5).

Suppose that the free wind velocity at hub height is $V_{100} = 14$ m/s, corresponding to $V_{10} = 9.8$ m/s in a neutral atmosphere in flat open grass land (roughness length 5 cm). Then in daytime ($m = 0.15$) the free wind velocity at the height of the lowest point of the rotor would be $V_{65} = 13.1$ m/s, at the height of the highest point $V_{135} = 14.6$ m/s (corresponding to velocities at the blade of $V_{65,b} = 8.7$ m/s and $V_{135,b} = 9.7$ m/s, respectively). The difference of 1.0 m/s between the low tip and hub height wind velocities causes a change in angle of attack on the blade of $\Delta\alpha = 0.55^\circ$. Between the high tip and hub height the change is smaller and of opposite sign: -0.3° . In a stable atmosphere ($m = 0.4$), at the same wind velocity at hub height, V_{65} is 11.8 m/s causing a change in angle of attack at the lower tip relative to hub height of 1.2° (at the high tip: $V_{135} = 15.8$ m/s, $\Delta\alpha = -1.0^\circ$). When the atmosphere is very stable ($m = 0.65$), wind velocity $V_{65} = 10.5$ m/s and the angle of attack on the low altitude tip deviates 1.9° from the angle at hub height (at the high tip: $V_{135} = 17.0$ m/s, $\Delta\alpha = -1.7^\circ$).

In fact when the lower tip passes the tower there is a greater mismatch between optimum and actual angle of attack α because there was already a change in angle of attack related to the wind velocity deficit in front of the tower. For a daytime atmosphere and with respect to the situation at hub

height, the change in α associated to a blade swish level of 2 ± 1 dB is estimated as $1.8 \pm 1.1^\circ$ (see appendix B.3), part of which (0.55°) is due to the wind profile and the rest to the tower. The increase in α due to the stability related wind profile change must be added to this daytime change in α . Thus, the change in angle of attack when the lower tip passes the mast is $1.8 \pm 1.1^\circ$ in daytime (unstable to neutral atmosphere), increasing to $2.5 \pm 1.1^\circ$ in a stable atmosphere and to $3.2 \pm 1.1^\circ$ in a very stable atmosphere. The associated change in TE sound level is 3.8 ± 1.7 dB for a stable and 4.8 ± 1.7 dB for a very stable atmosphere (compared to 2 ± 1 dB in daytime), which is the increase when the blade passes the tower. The corresponding total A-weighted sound level will be somewhat less as trailing edge sound is not the only sound source (but it is the dominant source: see section V.2.3).

At the high tip the change in angle of attack is smaller and of opposite sign with respect to the low tip, and also there is no (sudden) tower induced change to add to the wind gradient dependent change. The change in angle of attack at the high tip in a very stable atmosphere (-1.7°) is comparable to the change at the low tip in daytime, and this change is more gradual than for the low tip. This in fact lowers the sound emission from the high tip (with approximately 2 dB), most so when the high blade is vertical so just before and just after the low blade passes the tower, thereby in fact increasing the variation in swish sound level even more.

Thus we find that, for $v_{100} = 14$ m/s, the 1-2 dB daytime blade swish level increases to approximately 5 dB in a very stable atmosphere. The effect is stronger when wind velocity increases, up to the point where friction turbulence overrides stability and the atmosphere becomes neutral. The increase in trailing edge sound level will be accompanied by a lower peak frequency (see appendix B, equation B.2). For $\Delta\alpha = 5^\circ$ the shift is one octave.

b. Wind direction gradient. In a stable atmosphere air masses at different altitudes are only coupled by small scale turbulence and are therefore relatively independent. Apart from a higher velocity gradient a higher wind direction gradient is also possible, and with increasing height the wind

direction may change significantly. This wind direction shear will change the angle of attack with height. Assuming the wind at hub height to be normal to the rotor, the angle of attack will decrease below and increase above hub height (or vice versa). This effect, however, is small; if we suppose a change in wind direction of 20° over the rotor height at an induced wind velocity of 10 m/s , the change in angle of attack between extreme tip positions at 20 rpm is only 0.25° , which is negligible relative to the wind velocity shear.

c. Less turbulence. In a stable atmosphere turbines in a wind farm can run almost synchronously because the absence of large scale turbulence leads to less variation superimposed on the constant (average) wind velocity at each turbine. In unstable conditions the average wind velocity at the turbines will be equal, but instantaneous local wind velocities will differ because of the presence of large, turbulent eddies at the scale of the inter-turbine distance. In a stable atmosphere the turbulence scale decreases with a factor up to 10, relative to the neutral atmosphere and even more relative to an unstable atmosphere [Garratt 1992]. In stable conditions turbines in a wind farm therefore experience a more similar wind and as a consequence their instantaneous speeds are more nearly equal. This is confirmed by long term measurements by Nanaohara *et al.* [2004] who analysed coherence of wind velocities between different locations in two coastal areas. At night wind velocities at different locations were found to change more coherently than they did at daytime [Nanaohara 2004]. The difference between night and day was not very strong, probably because time of day on its own is not a sufficient indicator for stability.¹ The decay of coherence was strongly correlated with turbulence intensity, which in turn is closely correlated to stability.

Thus several turbines can be *nearly* synchronous: sometimes two or more turbines are in phase and the blade passing pulses coincide, then they go out of phase again. Synchronicity here refers to the sound pulses from the

¹ In a coastal location atmospheric stability also depends on wind direction as landwards stability is a diurnal, but seawards a seasonal phenomenon. Also, a fixed duration for all nights in a year does not coincide with the time that the surface cools (between sundown and sunrise), which is a prerequisite for stability.

different turbines as observed at the location of the observer: pulses synchronise when they arrive simultaneously. This is determined by differences in phase (rotor position) between turbines and in propagation distances of the sound from the turbines. Phase differences between turbine rotors occur because turbines are not connected and because of differences in actual performance. The place where synchronicity is observed will change when the phase difference between turbines changes. With exact synchronicity there would be a fixed interference pattern, with synchronicity at fixed spots. However, because of *near*-synchronicity, synchronous arrival of pulses will change over time and place and an observer will hear coinciding pulses for part of the time only.

Near a wind farm the variation in sound level will depend on the distances of the wind turbines relative to the observer: the level increase due to several turbines will reach higher levels when more turbines are at approximately equal distances and thus contribute equal immission levels. The increase in level variation, or beating, is thus at well-audible frequencies and has a repetition rate equal to the blade passing frequency.

A second effect of the decrease in turbulence strength is that in-flow turbulent sound level also decreases. The resulting decrease in sound level at frequencies below that of TE noise lowers the minimum in the temporal variations, thereby increasing modulation depth. The higher infrasound level due to extra blade loading is not perceptible because of the high hearing threshold at the very low blade passing frequency and its harmonics.

Thus, theoretically it can be concluded that in stable conditions (low ambient sound level, high turbine sound power and higher modulation or swish level) wind turbine sound can be heard at greater distances where it is of lower frequency due to absorption and the frequency shift of swish sound. It will thus be a louder and more low frequency 'thumping' sound and less the swishing sound that is observed close to a daytime wind turbine.

V.2 Measurement results

V.2.1 Locations

In the summer of 2002 and of 2004 wind turbine sound has been recorded in and near the Rhede wind farm (see section IV.1 for a specification of the turbines and a map of the area). In this chapter measurement results will be used from two locations: R and P (see figure IV.2). Location R is close to a dwelling west of the turbines, 625 m from the nearest turbine. The microphone position was at 4 m height and close to the house, but with no reflections except from the ground. Location P, 870 m south of R, was 1.5 m above a paved terrace in front of the façade of a dwelling at 750 m distance from the nearest turbine (in fact this is a short distance from the location P in chapter IV, which was not in front of the façade). The entire area is quiet, flat, agricultural land with some trees close to the dwellings. There is little traffic and there are no significant permanent human sound sources.

A third dwelling Z is in Boazum in the northern part of the Netherlands, 280 m west of a single, two-speed turbine (45 m hub height, 23 m blade length, 20/26 rpm). The area is again quiet, flat and agricultural, with some trees close to the dwelling. The immission measurement point is at 1.5 m height above gravel near dwelling Z. This measurement site is included here to show that the influence of stability on blade swish levels occurs also with smaller and single turbines. At all locations near dwellings the microphone was fitted in a 9 cm diameter foam wind screen.

Table V.1 gives an overview of measurement (start) time and date, of observed turbine speed and of wind velocity and direction, for situations of which results will be given below. The wind velocity at hub height V_{hub} has been determined from turbine rotation speed N or sound power level L_w (figure III.3, the relation $V_{hub} - N$ follows from [Kerkers 1999] and [Van den Berg 2002]). The wind velocity V_{10} was continuously measured at or near location A, except for location Z, where data from several meteorological stations were used showing that the wind was similar and nearly constant throughout the night of the measurement in the entire northern part of the Netherlands. In all cases there were no significant variations in wind velocity at the time of measurement. Wind velocity at

the microphone was lower than V_{10} because of the low microphone height and shelter provided by trees nearby. Wind direction is given in degrees relative to north and clockwise (90° is east).

The spectra near a turbine were measured with the microphone just above a hard surface at ground level 100 m downwind of a turbine in compliance with IEC 61400 [IEC 1998] as much as possible (non-compliance did not lead to differences in result; for reasons of non-compliance, see section II.4). The levels presented here are broad band immission levels: measured L_{eq} minus 6 dB correction for coherent reflection against the hard surface [IEC 1998]. The presented levels near the dwellings are also broad band immission levels: measured L_{eq} minus 3 dB correction for incoherent reflection at the façade for dwelling P, or measured L_{eq} without any correction for dwellings R and Z.

Table V.1: overview of measurement locations and times and of turbine speed and wind

Location	measurement date	time	turbine speed (rpm)	wind velocity (m/s)		wind direction ($^\circ$ north)
				V_{10}	V_{hub}	
Dwelling P	June 3, 2002	00:45	20	5	14	100
Turbine 7	June 3, 2002	06:30	19	5	15	100
Turbine 1	June 3, 2002	06:45	19	5	15	100
Dwelling R	Sep. 9, 2004	23:07	18	4	14	80
Turbine 16						
Dwelling Z	Oct. 18, 2003	01:43	26	3	6	60

At dwelling P at the time of measurement the beat in the turbine sound was very pronounced. In the other measurements (dwellings R and Z) the beating was not as loud. The measurements near turbine 16 and dwelling R at 23:07 on September 9 were performed simultaneously.

V.2.2 Frequency response of instruments

For the Rhode measurements in this chapter sound was recorded on a TASCAM DA-1 DAT-recorder with a precision 1" Sennheiser MKH 20

P48 microphone. The sound was then sampled in 1-second intervals on a Larson Davis 2800 frequency analyser. From 1 to 10 000 Hz the frequency response of the DAT-recorder and LD2800 analyser have been determined with a pure tone electrical signal as input. The LD2800 response is flat (± 1 dB) for all frequencies. The DAT-recorder is a first order high pass filter with a corner frequency of 2 Hz. The frequency response of the microphone was of most influence and has been determined relative to a B&K $\frac{1}{2}$ " microphone type 4189 with a known frequency response [B&K 1995]. Equivalent spectral sound levels with both microphones in the same sound field (10 cm mutual distance) were compared. For frequencies of 2 Hz and above the entire measurement chain is within 3 dB equivalent to a series of two high pass filters with corner frequencies of $f_1 = 4$ Hz and $f_2 = 9$ Hz, or a transfer function equal to $-10 \cdot \log[1+(f_1/f)^2] -10 \cdot \log[1+(f_2/f)^2]$. For frequencies below 2 Hz this leads to high signal reductions (< -40 dB) and consequentially low signal to (system) noise ratios. Therefore values at frequencies < 2 Hz are not presented.

For the Boazum measurements sound was recorded on a Sharp MD-MT99 minidisc recorder with a 1" Sennheiser ME62 microphone. The frequency response of this measurement chain is not known, but is assumed to be flat in the usual audio frequency range. Simultaneous measurement of the broad band A-weighted sound level were done with a precision (type 1) 01dB sound level meter. Absolute precision is not required here as the minidisc recorded spectra are only used to demonstrate relative spectral levels. Because of the ATRAC time coding of a signal, a minidisc recording does not accurately follow a level change in a time interval < 11.6 ms. This is insignificant in the present case as the 'fast' response time of a sound level meter is much slower (125 ms).

V.2.3 Measured emission and immission spectra

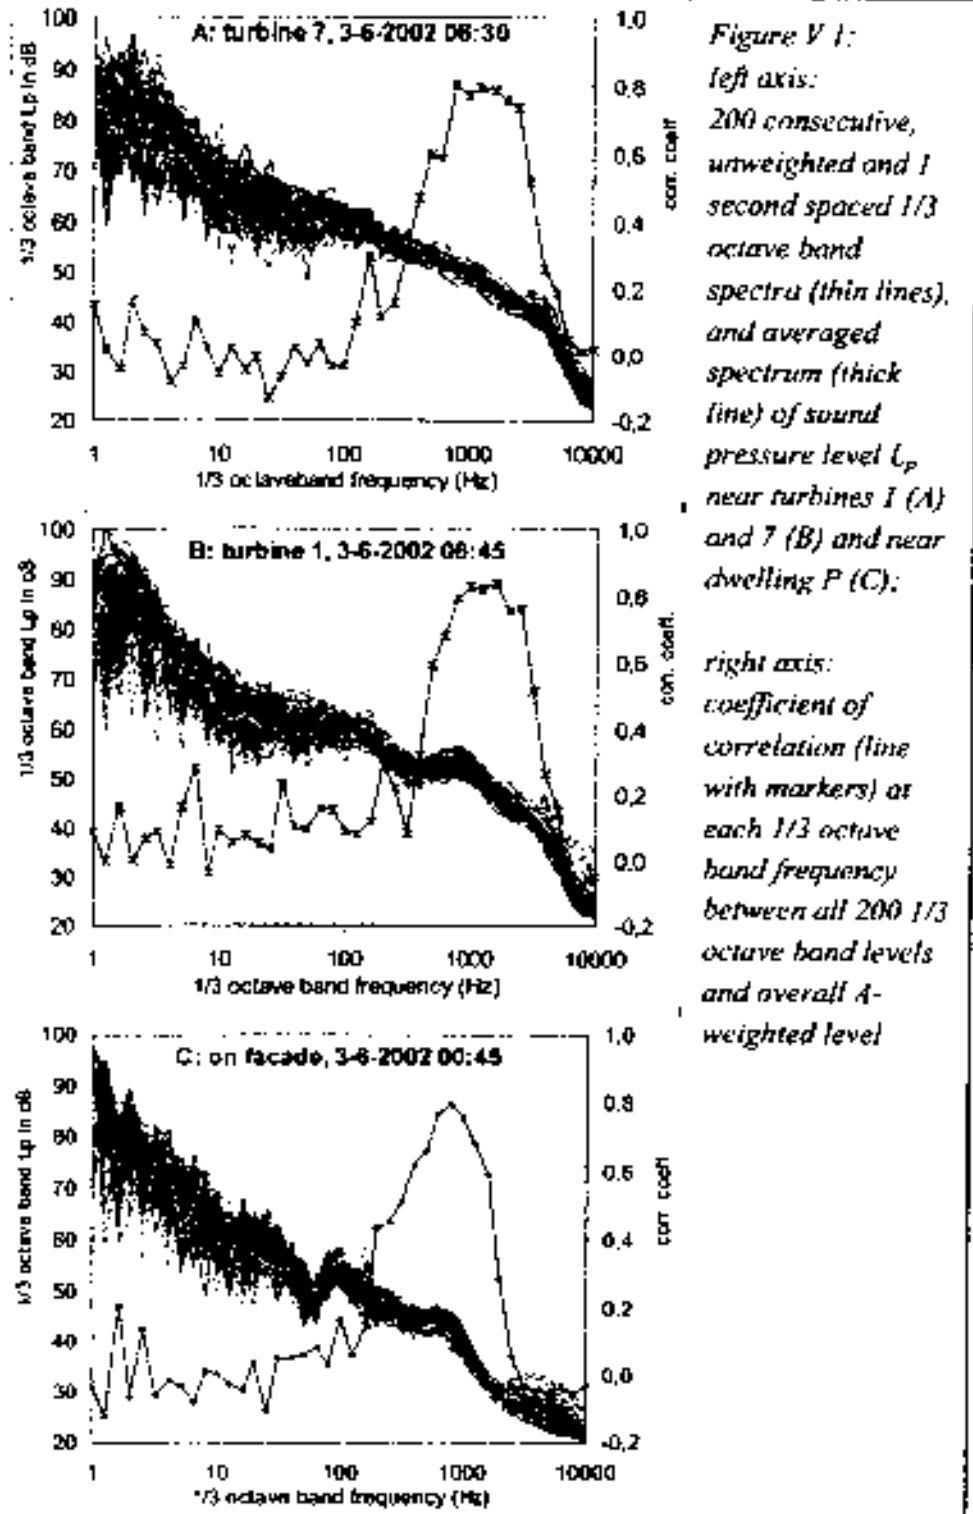

Recordings were made at evening, night or early morning. On June 3, 2002, sound was recorded at dwelling P at around midnight and early in the morning near two turbines (numbers 1 and 7 in figure IV.1). At P at these times a distinct beat was audible in the wind turbine sound. In figure V.1, 1/3 octave band spectra of the recorded sound at P and at both

turbines have been plotted. In each figure A, B and C, 200 sound pressure spectra sampled in one-second intervals, as well as the energy averaged spectrum of the 200 samples have been plotted. The standard deviation of 1/3 octave band levels is typically 7 dB at very low frequencies, decreasing to approx. 1 dB at 1 kHz. The correlation coefficient ρ between all 200 unweighted 1/3 octave band levels and the overall A-weighted sound level has also been plotted for each 1/3 octave band frequency.

For frequencies below approximately 10 Hz the sound is dominated by the thickness sound associated with the blade passing frequency and harmonics. In the rest of the infrasound region and upwards, in-flow turbulence is the dominant sound producing mechanism. Gradually, at frequencies above 100 Hz, trailing edge sound becomes the most dominant source, declining at high frequencies of one to several kHz. Trailing edge sound is more pronounced at turbine 1 (T1) compared to turbine 7 (T7), causing a hump near 1000 Hz in the T1 spectra. At very high frequencies (> 2 kHz) sometimes spectral levels are influenced by birds' sounds.

It is clear from the spectra that most energy is found at lower frequencies. However, most of this sound is not perceptible. To assess the infrasound level relevant to human perception it can be expressed as a G-weighted level [ISO 1995]. With G-weighting sound above the infrasound range is suppressed. The average infrasound perception threshold is 95 dB(G) [Jakobsen 2004]. The measured G-weighted levels are 15-20 dB below this threshold: 80.5 and 81.1 dB(G) near turbines 1 and 7 respectively, and 76.4 dB(G) at the façade.

The correlations show that variations in total A-weighted level near the turbines are correlated with the 1/3 octave band levels with frequencies from 400 through 3150 Hz (where $\rho > 0.4$), which is trailing edge sound. This is one octave lower (200 - 1600 Hz) for the sound at the façade: the higher frequencies were better absorbed during propagation through the atmosphere.

The façade spectra in figure V.1C show a local minimum at 50-63 Hz, followed by a local maximum at 80-100 Hz.¹ This is caused by interference between the direct sound wave and the wave reflected by the façade at 1.5 m from the microphone: for wave lengths of approximately 6 m (55 Hz) this leads to destructive interference, for wave lengths of 3 m (110 Hz) to constructive interference.

In figure V.2A the three average spectra at the same locations as in figure V.1A-C have been plotted, but now for a total measurement time of 9.5 (façade), 5 (T7) and 6 (T1) minutes. For each of these measurement periods the average of the 5% of samples with the highest broad band A-weighted sound level (*i.e.* the equivalent spectral level of the L_{A5} percentile) has also been plotted, as well as the 5% of samples with the lowest broad band level (L_{A95}). The range in A-weighted broad band level can be defined as the difference between the highest and lowest value: $R_{bb} = L_{Amax} - L_{Amin}$. Similarly the range per 1/3 octave or octave band R_f can be defined by the difference in spectral levels corresponding to L_{Amax} and L_{Amin} . The difference between L_{A5} and L_{A95} is a more stable value, avoiding possibly incidental extreme values, especially when spectral data are used. $R_{bb,90}$ is defined as the difference in level between the 5% highest and the 5% lowest broad band sound levels: $R_{bb,90} \approx L_{A5} - L_{A95}$. For spectral data, $R_{f,90}$ is the difference between spectral levels associated with L_{A5} and L_{A95} . Values of $R_{f,90}$ are plotted in the lower part of figure V.2A (here octave band levels have been used to avoid the somewhat 'jumpy' behaviour of the 1/3 octave band levels). Close to turbines 1 and 7 R_{bb} is 4.8 and 4.1 dB, respectively. $R_{bb,90}$ is 3.2 and 2.6 dB, which is almost the same as $R_{f,90}$ (3.2 and 3.0 dB) at 1000-4000 Hz. Further away, at the façade, R_{bb} is comparable to the near turbine values: 4.9 dB. $R_{bb,90}$ at the façade is 3.3 dB and again almost the same as maximum $R_{f,90}$ (3.5 dB) at 1000 Hz.

Also, close to the turbine there is a low frequency maximum in $R_{f,90}$ at 2 (or 8) Hz that is also present at the façade, indicating that the modulation of trailing edge sound is correlated in time with the infrasound caused by the blade movement.

¹ In an FFT spectrum minima are at 57 and 170 Hz, maxima at 110 and 220 Hz

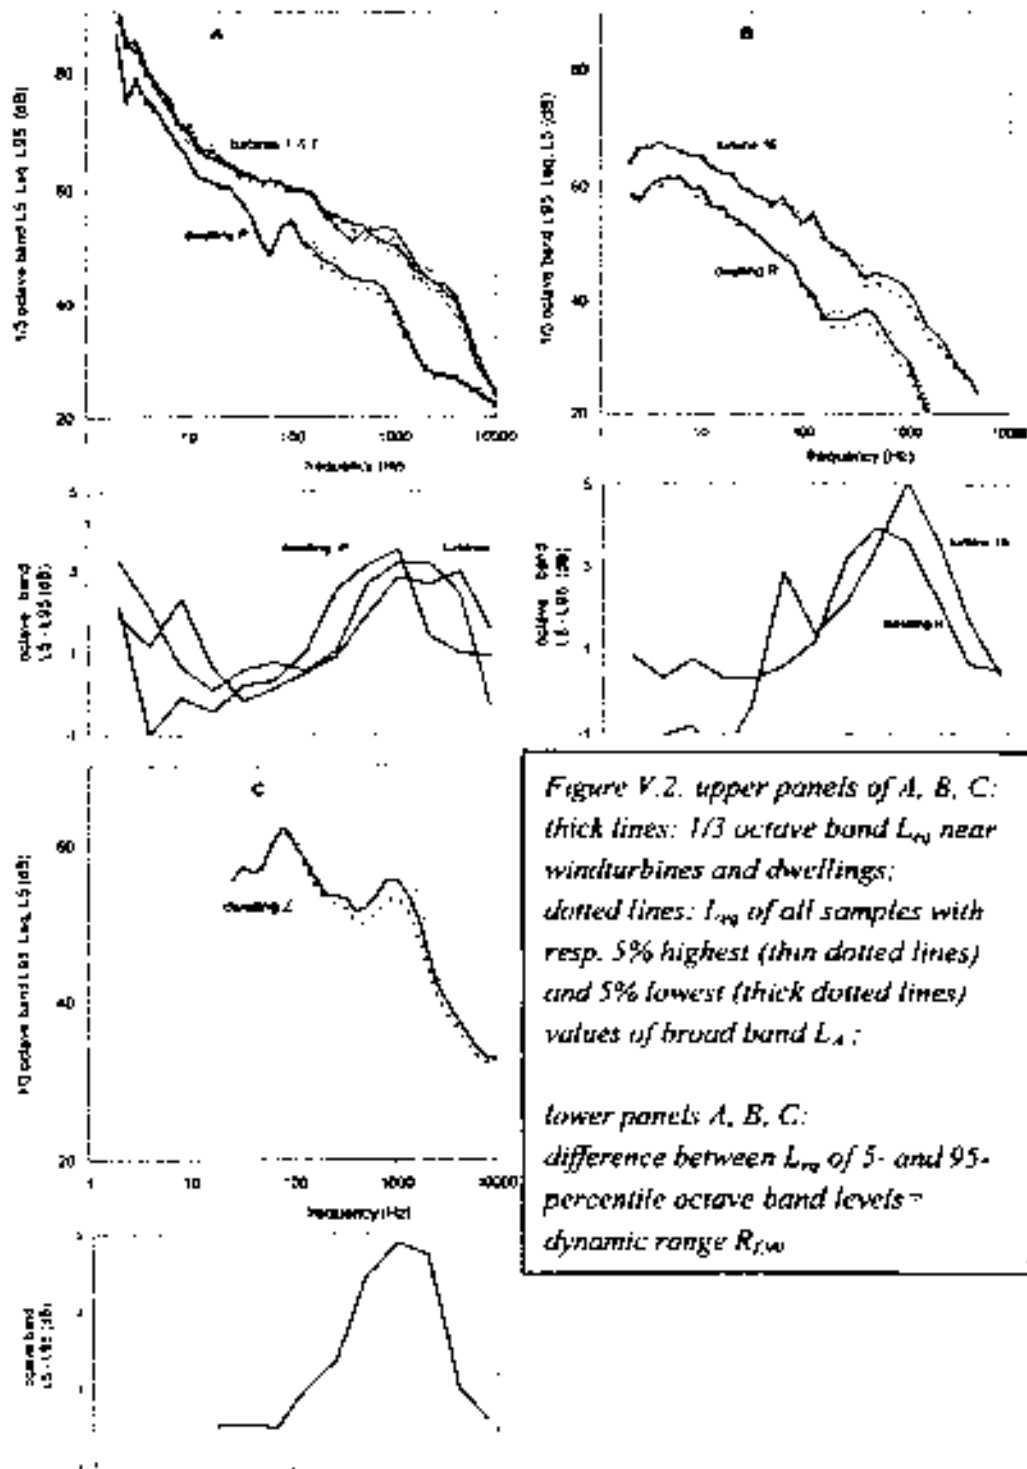

Figure V.2B presents similar plots for the average spectra and the L_{A5} and L_{A95} spectra at dwelling R and near turbine T16, simultaneously over a period of 16 minutes. Close to the turbine the broadband R_{bb} is 6.2 dB and $R_{bb,90}$ is 3.7 dB; octave band $R_{f,90}$ is highest (5.1 dB) at 1000 Hz. Near R broad band $R_{bb,90}$ is also 3.7 dB, and octave band $R_{f,90}$ is highest (4.0 dB) at 500 Hz. The R_{bb} ranges are 2.3–2.5 dB higher than the 90% ranges $R_{bb,90}$. In the measurements at this time and place (dwelling R) the infrasound level was lower than in the previous measurements at dwelling P where beating was more pronounced. G-weighted sound level during the 16 minutes at R was 70.4 dB(G), and at T16 77.1 dB(G).

Finally figure V.2C gives average spectra over a period of 16 minutes at dwelling Z. $R_{f,90}$ is now highest (4.8 dB) at 1 kHz, and broadband $R_{bb,90}$ is 4.3 dB ($R_{bb} \approx 5.9$ dB). The turbine near Z is smaller and lower, but rotates faster than the Rhede turbines; for a hub height wind velocity of 6 m/s the expected calculated increase in trailing edge sound for the lower tip relative to the day time situation is 2.0 ± 0.8 dB for a stable, and 2.9 ± 0.8 dB for a very stable atmosphere. For this turbine a peak trailing edge sound level is expected (according to equation B.2 in appendix B) at a frequency of $1550/b$ Hz $\approx 400 - 800$ Hz.

In all cases above the measured sound includes ambient background sound. Ambient background sound level could not be determined separately at the same locations because the wind turbine(s) could not be stopped (see section II.4). However, at audible frequencies it could be ascertained by ear that wind turbine sound was dominant. At infrasound frequencies this could not be ascertained. But if significant ambient sound were present, subtracting it from the measured levels would lead to lower (infrasound) sound levels, which would not change the conclusion, based on the G-weighted level, that measured infrasound must be considered inaudible.

A 25 second part of the 16 min period that corresponds with the spectra in figure V.2B is shown in figure V.3. The broad band level L_A changes with time at T16 and R, showing a more or less regular variation with a period of approximately 1 s ($\approx 1/f_B$). Note that the level differences at R are of the

same magnitude as close to the turbine, but the fluctuations at R consist of narrow peaks in comparison to the broader near-turbine fluctuations.

V.2.4 Beats caused by interaction of several wind turbines

In the previous section we saw that measured variations in broad band sound level (R_{bb}) were 4 to

6 dB. In figure V.4 a registration is given of the sound pressure level every 50 msec over a 180 seconds period, taken from a DAT-recording on a summer night (June 3rd, 0:40 h) on a terrace of dwelling P at 750 m west of the westernmost row of wind turbines (this sound includes the reflection on the façade). In this night stable conditions prevailed ($m = 0.45$ from the wind velocities in table V.1). Turbines 12 and 11 are closest at 710 and 750 m, followed by turbines 9 and 14 at 880 and 910 m. Other turbines are more than 1 km distant and have an at least 4 dB lower immission level than the closest turbine has.

In figure V.4 there is a slow variation of the 'base line' (minimum levels) probably caused by variations in wind velocity and atmospheric sound transmission. There is furthermore a variation in dynamic range: a small difference between subsequent maximum and minimum levels of less than 2 dB is alternated by larger differences.
